# Introduction to Optimization <br> Lecture 6: Continuous Optimization III (Gradient-based Optimization) 

October 30, 2015<br>TC2 - Optimisation<br>Université Paris-Saclay

Anne Auger<br>INRIA Saclay - Ile-de-France<br>Dimo Brockhoff<br>INRIA Lille - Nord Europe

## Course Overview

| Date |  | Topic |
| :--- | :--- | :--- |
| Fri, 18.9.2015 | DB | Introduction and Greedy Algorithms |
| Fri, 25.9.2015 | DB | Dynamic programming and Branch and Bound |
| Fri, 2.10.2015 | DB | Approximation Algorithms and Heuristics |
| Fri, 9.10.2015 | AA | Introduction to Continuous Optimization |
| Fri, 16.10.2015 | AA | Introduction to Continuous Optimization II |
|  |  |  |
| Fri, 30.10.2015 | AA | Gradient-Based Algorithms |
| Fri, 6.11.2015 | AA | Stochastic Algorithms and Derivative-free Optimization |
| 20.11.2015 |  |  |

## all classes + exam are from 14h till 17h15 (incl. a 15min break) here in PUIO-D101/D103

## Constrained Optimization

## Equality Constraint

## Objective:

Generalize the necessary condition of $\nabla f(x)=0$ at the optima of $\mathfrak{f}$ when $f$ is in $\mathcal{C}^{1}$, i.e. is differentiable and its differential is continuous

Theorem:
Be $U$ an open set of $(E,\| \|)$, and $f: U \rightarrow \mathbb{R}, g: U \rightarrow \mathbb{R}$ in $\mathcal{C}^{1}$. Let $a \in E$ satisfy

$$
\left\{\begin{array}{c}
f(a)=\inf \left\{f(x) \mid x \in \mathbb{R}^{n}, g(x)=0\right\} \\
g(a)=0
\end{array}\right.
$$

i.e. $a$ is optimum of the problem

If $\nabla g(a) \neq 0$, then there exists a constant $\lambda \in \mathbb{R}$ called Lagrange multiplier, such that
$\underbrace{\nabla f(a)+\lambda \nabla g(a)=0}$ Euler - Lagrange equation
i.e. gradients of $f$ and $g$ in $a$ are colinear

## Geometrical Interpretation Using an Example

## Exercise:

Consider the problem

$$
\inf \left\{f(x, y) \mid(x, y) \in \mathbb{R}^{2}, g(x, y)=0\right\}
$$

$$
f(x, y)=y-x^{2} \quad g(x, y)=x^{2}+y^{2}-1=0
$$

1) Plot the level sets of $f$, plot $g=0$
2) Compute $\nabla f$ and $\nabla g$
3) Find the solutions with $\nabla f+\lambda \nabla g=0$
equation solving with 3 unknowns ( $x, y, \lambda$ )
4) Plot the solutions of 3 ) on top of the level set graph of 1 )

## Interpretation of Euler-Lagrange Equation

Intuitive way to retrieve the Euler-Lagrange equation:

- In a local minimum $a$ of a constrained problem, the hypersurfaces (or level sets) $f=f(a)$ and $g=0$ are necessarily tangent (otherwise we could decrease $f$ by moving along $g=0$ ).
- Since the gradients $\nabla f(a)$ and $\nabla g(a)$ are orthogonal to the level sets $f=f(a)$ and $g=0$, it follows that $\nabla f(a)$ and $\nabla g(a)$ are colinear.

## Generalization to More than One Constraint

## Theorem

- Assume $f: U \rightarrow \mathbb{R}$ and $g_{k}: U \rightarrow \mathbb{R}(1 \leq k \leq p)$ are $\mathcal{C}^{1}$.
- Let $a$ be such that

$$
\left\{\begin{array}{r}
f(a)=\inf \left\{f(x) \mid x \in \mathbb{R}^{n}, \quad g_{k}(x)=0, \quad 1 \leq k \leq p\right\} \\
g_{k}(a)=0 \text { for all } 1 \leq k \leq p
\end{array}\right.
$$

- If $\left(\nabla g_{k}(a)\right)_{1 \leq k \leq p}$ are linearly independent, then there exist $p$ real constants $\left(\lambda_{k}\right)_{1 \leq k \leq p}$ such that

$$
\nabla f(a)+\sum_{k=1 \uparrow}^{p} \lambda_{k} \nabla g_{k}(a)=0
$$

## The Lagrangian

- Define the Lagrangian on $\mathbb{R}^{n} \times \mathbb{R}^{p}$ as

$$
\mathcal{L}\left(x,\left\{\lambda_{k}\right\}\right)=f(x)+\sum_{k=1}^{p} \lambda_{k} g_{k}(x)
$$

- To find optimal solutions, we can solve the optimality system
$\left\{\right.$ Find $\left(x,\left\{\lambda_{k}\right\}\right) \in \mathbb{R}^{n} \times \mathbb{R}^{p}$ such that $\nabla f(x)+\sum_{k=1}^{p} \lambda_{k} \nabla g_{k}(x)=0$

$$
g_{k}(x)=0 \text { for all } 1 \leq k \leq p
$$

$$
\Leftrightarrow\left\{\begin{array}{c}
\text { Find }\left(x,\left\{\lambda_{k}\right\}\right) \in \mathbb{R}^{n} \times \mathbb{R}^{p} \text { such that } \nabla_{x} \mathcal{L}\left(x,\left\{\lambda_{k}\right\}\right)=0 \\
\nabla_{\lambda_{k}} \mathcal{L}\left(x,\left\{\lambda_{k}\right\}\right)(x)=0 \text { for all } 1 \leq k \leq p
\end{array}\right.
$$

## Inequality Constraint: Definitions

Let $U=\left\{x \in \mathbb{R}^{n} \mid g_{k}(x)=0\right.$ (for $k \in E$ ), $g_{k}(x) \leq 0$ (for $k \in I$ ) $\}$.

## Definition:

The points in $\mathbb{R}^{n}$ that satisfy the constraints are also called feasible points.

## Definition:

Let $a \in U$, we say that the constraint $g_{k}(x) \leq 0$ (for $k \in I$ ) is active in $a$ if $g_{k}(a)=0$.

## Inequality Constraint: Karush-Kuhn-Tucker Theorem

Theorem (Karush-Kuhn-Tucker, KKT):
Let $U$ be an open set of $(E,\| \|)$ and $f: U \rightarrow \mathbb{R}, g_{k}: U \rightarrow \mathbb{R}$, all $\mathcal{C}^{1}$
Furthermore, let $a \in U$ satisfy

$$
\left\{\begin{array}{c}
f(a)=\inf \left(f(x) \mid x \in \mathbb{R}^{n}, g_{k}(x)=0(\text { for } k \in E), g_{k}(x) \leq 0(\text { for } k \in \mathrm{I})\right. \\
g_{k}(a)=0(\text { for } k \in E) \\
g_{k}(a) \leq 0(\text { for } k \in I)
\end{array}\right.
$$

Let $I_{a}^{0}$ be the set of constraints that are active in $a$. Assume that $\left(\nabla g_{k}(a)\right)_{k \in E \cup I_{a}^{0}}$ are linearly independent.
Then there exist $\left(\lambda_{k}\right)_{1 \leq k \leq p}$ that satisfy

$$
\left\{\begin{array}{c}
\nabla f(a)+\sum_{k=1}^{p} \lambda_{k} \nabla g_{k}(a)=0 \\
g_{k}(a) \stackrel{=}{=}(\text { for } k \in E) \\
g_{k}(a) \leq 0(\text { for } k \in I) \\
\lambda_{k} \geq 0\left(\text { for } k \in I_{a}^{0}\right) \\
\lambda_{k} g_{k}(a)=0(\text { for } k \in E \cup I)
\end{array}\right.
$$

## Inequality Constraint: Karush-Kuhn-Tucker Theorem

Theorem (Karush-Kuhn-Tucker, KKT):
Let $U$ be an open set of $(E,\| \|)$ and $f: U \rightarrow \mathbb{R}, g_{k}: U \rightarrow \mathbb{R}$, all $\mathcal{C}^{1}$
Furthermore, let $a \in U$ satisfy

$$
\left\{\begin{array}{c}
f(a)=\inf \left(f(x) \mid x \in \mathbb{R}^{n}, g_{k}(x)=0(\text { for } k \in E), g_{k}(x) \leq 0(\text { for } k \in \mathrm{I})\right. \\
g_{k}(a)=0(\text { for } k \in E) \\
g_{k}(a) \leq 0(\text { for } k \in I)
\end{array}\right.
$$

Let $I_{a}^{0}$ be the set of constraints that are active in $a$. Assume that $\left(\nabla g_{k}(a)\right)_{k \in E \cup I_{a}^{0}}$ are linearly independent.
Then there exist $\left(\lambda_{k}\right)_{1 \leq k \leq p}$ that satisfy

$$
\left\{\begin{array}{c}
\nabla f(a)+\sum_{k=1}^{p} \lambda_{k} \nabla g_{k}(a)=0 \\
g_{k}(a)=0(\text { for } k \in E) \\
g_{k}(a) \leq 0(\text { for } k \in I) \\
\lambda_{k} \geq 0\left(\text { for } k \in I_{a}^{0}\right) \\
\lambda_{k} g_{k}(a)=0(\text { for } k \in E \cup I)
\end{array}\right.
$$

either active constraint or $\lambda_{k}=0$

## Descent Methods

## Descent Methods

## General principle

(1) choose an initial point $x_{0}$, set $t=1$
(2) while not happy

- choose a descent direction $\boldsymbol{d}_{t} \neq 0$
- line search:
- choose a step size $\sigma_{t}>0$
- set $\boldsymbol{x}_{t+1}=\boldsymbol{x}_{t}+\sigma_{t} \boldsymbol{d}_{t}$
- set $t=t+1$

## Remaining questions

- how to choose $\boldsymbol{d}_{t}$ ?
- how to choose $\sigma_{t}$ ?

## Gradient Descent

Rationale: $\boldsymbol{d}_{t}=-\nabla f\left(\boldsymbol{x}_{t}\right)$ is a descent direction indeed for $f$ differentiable

$$
\begin{aligned}
f(x-\sigma \nabla f(x)) & =f(x)-\sigma \| \nabla f(x)| |^{2}+o(\sigma\|\nabla f(x)\|) \\
< & f(x) \text { for } \sigma \text { small enough }
\end{aligned}
$$

## Step-size

- optimal step-size: $\sigma_{t}=\operatorname{argmin} f\left(\boldsymbol{x}_{t}-\sigma \nabla f\left(\boldsymbol{x}_{t}\right)\right)$
- Line Search: total or partial optimization w.r.t. $\sigma$

Total is however often too "expensive" (needs to be performed at each iteration step)
Partial optimization: execute a limited number of trial steps until a loose approximation of the optimum is found. Typical rule for partial optimization: Armijo rule
see mid-term exam

## Stopping criteria:

norm of gradient smaller than $\epsilon$

## Gradient Descent: Simple Theoretical Analysis

Assume $f$ is twice continuously differentiable, convex and that $\mu I_{d} \leqslant \nabla^{2} f(x) \leqslant L I_{d}$ with $\mu>0$ holds, assume a fixed step-size $\sigma_{t}=\frac{1}{L}$ Note: $A \preccurlyeq B$ means $x^{T} A x \leq x^{T} B x$ for all $x$

$$
\begin{gathered}
x_{t+1}-x^{*}=x_{t}-x^{*}-\sigma_{t} \nabla^{2} f\left(y_{t}\right)\left(x_{t}-x^{*}\right) \text { for some } y_{t} \in\left[x_{t}, x^{*}\right] \\
x_{t+1}-x^{*}=\left(I_{d}-\frac{1}{L} \nabla^{2} f\left(y_{t}\right)\right)\left(x_{t}-x^{*}\right)
\end{gathered}
$$

$$
\text { Hence }\left\|x_{t+1}-x^{*}\right\|^{2} \leq\| \| I_{d}-\frac{1}{L} \nabla^{2} f\left(y_{t}\right)\| \|^{2}\left\|x_{t}-x^{*}\right\|^{2}
$$

$$
\leq\left(1-\frac{\mu}{L}\right)^{2}\left\|x_{t}-x^{*}\right\|^{2}
$$

Linear convergence: $\left\|x_{t+1}-x^{*}\right\| \leq\left(1-\frac{\mu}{L}\right)\left\|x_{t}-x^{*}\right\|$
algorithm slower and slower with increasing condition number
Non-convex setting: convergence towards stationary point

## Newton Algorithm

## Newton Method

- descent direction: $-\left[\nabla^{2} f\left(x_{k}\right)\right]^{-1} \nabla f\left(x_{k}\right)$ [so-called Newton direction]
- The Newton direction:
- minimizes the best (locally) quadratic approximation of $f$ :

$$
\tilde{f}(x+\Delta x)=f(x)+\nabla f(x)^{T} \Delta x+\frac{1}{2}(\Delta x)^{T} \nabla^{2} f(x) \Delta \mathrm{x}
$$

- points towards the optimum on $f(x)=\left(x-x^{*}\right)^{T} A\left(x-x^{*}\right)$
- however, Hessian matrix is expensive to compute in general and its inversion is also not easy

## Affine Invariance

Affine Invariance: same behavior on $f(x)$ and $f(A x+b)$ for $A \in$ GLn(R)

- Newton method is affine invariant

$$
\begin{array}{r}
\text { see http: //users.ece.utexas.edu/~cmcaram/EE381V_2012F/ } \\
\text { Lecture_6_Scribe_Notes.final.pdf }
\end{array}
$$

- same convergence rate on all convex-quadratic functions
- Gradient method not affine invariant

## Quasi-Newton Method: BFGS

$x_{t+1}=x_{t}-\sigma_{t} H_{t} \nabla f\left(x_{t}\right)$ where $H_{t}$ is an approximation of the inverse Hessian

## Key idea of Quasi Newton:

successive iterates $x_{t}, x_{t+1}$ and gradients $\nabla f\left(x_{t}\right), \nabla f\left(x_{t+1}\right)$ yield second order information

$$
\begin{gathered}
q_{t} \approx \nabla^{2} f\left(x_{t+1}\right) p_{t} \\
\text { where } p_{t}=x_{t+1}-x_{t} \text { and } q_{t}=\nabla f\left(x_{t+1}\right)-\nabla f\left(x_{t}\right)
\end{gathered}
$$

Most popular implementation of this idea: Broyden-Fletcher-Goldfarb-Shanno (BFGS)

- default in MATLAB's fminunc and python's scipy.optimize.minimize
