#### Abstract

We investigate the kinetic theory of partially ionized reactive gas mixtures in strong magnetic fields following [Physica A 327 (2003) 313-348]. A new tensor basis is introduced for expanding the perturbed distribution functions associated with the viscous tensor. New symmetry properties of transport coefficients are established as well as simplified bracket expressions. A variational framework is introduced for a direct evaluation of the thermal conductivity and the thermal diffusion ratios. The transport linear systems corresponding to the usual Sonine/Wang-Chang Uhlenbeck polynomial expansions are evaluated. The behavior of transport coefficients and transport fluxes for vanishing magnetic fields is investigated using series expansions. Practical implementation of iterative algorithms for solving the resulting complex symmetric constrained singular transport linear systems are discussed as well as various aproximations of the transport coefficients.

## 1 Introduction

Ionized magnetized reactive gas mixtures have many practical applications such laboratory plasmas, high-speed gas flows, lean flame stabilization or atmospheric phenomena $[3,7,9,11,12,21,37]$. Application of the Chapman-Enskog theory to partially ionized mixtures of monatomic gases in the presence of electric and magnetic fields has been discussed in particular by Chapman and Cowling [9] and Ferziger and Kaper [21] in a regime where there is only one temperature in the mixture, assuming that the electric field is not intense [10, 21, 25]. The proper collision operator to be used is then the Boltzmann collision operator with shielded potentials [21]. Mixtures of monatomic gases at thermodynamic nonequilibrium with multitemperature transport-arising from small electron/ion mass ratio asymptotics-have also been investigated by Chmieleski and Ferziger [10], and in the fully ionized case by Braginsky using Landau equation [3, 4]. Higher order evaluations of transport coefficients have been performed by Kaneko and coworkers for binary neutral mixtures in uniform magnetic fields in a simplified steady kinetic framework [31, 32]. Convergence properties of the Chapman-Enskog expansion for transport coeffients of magnetized argon plasmas have been investigated by Bruno and coworkers $[5,6,7]$. The degree of anisotropy of various transport coefficients introduced by the magnetic field has been studied in terms of the electron Hall parameter. Bruno and coworkers have established in particular the important influence of the Ramsauer mimimun in the electron-Argon cross sections [6, 7].

In a recent paper [25], the authors have investigated the kinetic theory of partially ionized magnetized polyatomic reactive gas mixtures. The macroscopic equations in the zeroth-order and first-order regimes, together with expressions for the transport fluxes and the transport coefficients, have been obtained. New bracket expressions have been established for the perpendicular and transverse diffusion, thermal diffusion and partial thermal conductivity coefficients as well as for the shear viscosity coefficients. A new definition of the thermal conductivity and of the thermal diffusion ratios-consistent with the zero magnetic fields limit-has also been introduced. Positivity properties of multicomponent diffusion matrices have been investigated and the mathematical structure of the transport linear systems has also been addressed.

We further investigate in this paper the kinetic theory of partially ionized reactive gas mixtures in the strong magnetic field regime. A new tensor basis is first introduced for expanding the anisotropic perturbed species distribution functions associated with the viscous tensor which has better properties than the linearly dependent generating family previously used [21, 25]. This new basis is constituted of five independent traceless symmetric tensors constructed with the particle velocity vector and the mag-
netic field pseudo vector. These five tensors are orthogonal to collisional invariants and the derivation of the corresponding linearized integral equations and transport linear systems is clarified.

New simplified bracket expressions for diffusion, thermal diffusion and partial thermal conductivity coefficients are also obtained from which we deduce new symmetry properties of these transport coefficients. These symmetry properties result from clever manipulations of the real and imaginary parts of Boltzmann linearized complex integral equations. As a consequence, we also simplify the positivity properties of the resulting multicomponent diffusion matrices and heat-mass transport matrices parallel, perpendicular and transverse to the magnetic field.

Generalizing previous work on non ionized species [15] we further introduce a variational framework for a direct evaluation of the thermal conductivities and the thermal diffusion ratios without the intermediate evaluation of the partial thermal conductivities and the thermal diffusion coefficients. The resulting transport linear systems are of reduced size which is more interesting from a computational point of view.

All transport linear systems corresponding to the first usual Sonine/Wang-Chang Uhlenbeck polynomial expansions are evaluated, making use of previous work on neutral species mixtures [14]. The mathematical structure of the transport linear systems is discussed as well as the evaluation of the corresponding transport coefficients parallel, perpendicular and transverse to the magnetic field.

Since the size of the transport linear systems can be relatively large and since the transport coefficients have to be evaluated at each computational cell in space and time, transport property evaluation may become computationally expensive, especially for multidimensional numerical simulations. In this regard, the use of iterative techniques has been shown to be an interesting and appealing alternative $[14,16,17]$. We discuss practical implementation of iterative techniques for solving the resulting complex symmetric constrained singular transport linear systems. The accuracy of various approximated transport coefficients is investigated and numerical tests are performed for weakly ionized air at 10000 K .

The behavior of all transport coefficients and of anisotropic transport fluxes for vanishing magnetic fields is finally investigated using series expansions in terms of the intensity of the magnetic field. These series expansions show that, for vanishing magnetic field, the mass and heat fluxes as well as the viscous tensor behave smoothly. Onsager reciprocal relations are also more closely investigated for anisotropic transport fluxes in particular for the viscous tensor.

## 2 Theoretical framework

In this section, we summarize the theoretical kinetic framework for polyatomic reactive gas mixtures in the presence of electric and magnetic fields.

### 2.1 Generalized Boltzmann equation

We consider a dilute reactive gas mixture composed of $n^{s}$ chemical species having internal degrees of freedom. The Boltzmann equations for polyatomic gas mixtures are written in a semi-classical framework with degeneracy averaged collision cross sections [38] and the chemical source terms is taken from [33, 2, 18, 29].

The state of the mixture is described by the species distribution functions denoted by $f_{i}\left(t, \boldsymbol{x}, \boldsymbol{c}_{i}, \mathrm{I}\right)$, where $i$ is the index of the species, $t$ the time, $\boldsymbol{x}$ the three-dimensional spatial coordinate, $\boldsymbol{c}_{i}$ the velocity and I the index for the internal energy state of the $i$ th species. We denote by $\mathcal{S}$ the species indexing set $\mathcal{S}=\left\{1, \ldots, n^{s}\right\}$, by $m_{i}, e_{i}$, and $z_{i}=e_{i} / m_{i}$ the molecular mass, charge, and charge per unit mass of the $i$ th species, and finally by $\mathcal{E}_{i \text { I }}$ the internal energy of the $i$ th species in the ith state. For a family of functions $\xi_{i}, i \in \mathcal{S}$, we will use the compact notation $\xi=\left(\xi_{i}\right)_{i \in \mathcal{S}}$.

The family of species distribution functions $f=\left(f_{i}\right)_{i \in \mathcal{S}}$ is the solution of the generalized Boltzmann equations

$$
\begin{equation*}
\widetilde{\mathcal{D}}_{i}\left(f_{i}\right)+\frac{1}{\epsilon^{\mathrm{b}}} \widehat{\mathcal{D}}_{i}\left(f_{i}\right)=\frac{1}{\epsilon} \mathcal{S}_{i}(f)+\epsilon^{\mathrm{a}} \mathcal{C}_{i}(f), \quad i \in \mathcal{S} \tag{1}
\end{equation*}
$$

${\underset{\sim}{w}}^{\text {where }} \widetilde{\mathcal{D}}_{i}$ is the streaming operator $\widetilde{\mathcal{D}}_{i}\left(f_{i}\right)=\partial_{t} f_{i}+\boldsymbol{c}_{i} \cdot \boldsymbol{\partial}_{\boldsymbol{x}} f_{i}+\widetilde{\boldsymbol{b}}_{i} \cdot \boldsymbol{\partial}_{\boldsymbol{c}_{i}} f_{i}$ associated with the reduced force $\widetilde{\boldsymbol{b}}_{i}=\boldsymbol{g}+z_{i}(\boldsymbol{E}+\boldsymbol{v} \wedge \boldsymbol{B})$, where $\boldsymbol{g}$ is a species independent external force, $\boldsymbol{E}$ the electric field, $\boldsymbol{B}$ the magnetic field, and $\widehat{\mathcal{D}}_{i}\left(f_{i}\right)=z_{i}\left(\left(\boldsymbol{c}_{i}-\boldsymbol{v}\right) \wedge \boldsymbol{B}\right) \cdot \boldsymbol{\partial}_{\boldsymbol{c}_{i}} f_{i}$. The reactive source term $\mathcal{C}_{i}(f)$ and the nonreactive
source term $\mathcal{S}_{i}(f)$ are described in [38, 14, 18, 25] and are both compatible with the $H$-theorem [18]. In these equations, $\epsilon$ is the usual formal parameter associated with Enskog expansion, and a and b are positive integers which depend on the regime under consideration. In this paper, we only consider the strong magnetic field regime $\mathrm{b}=1$ and the Maxwellian reaction regime $\mathrm{a}=1$ and we refer to [18, 24, 25] for more details on other regimes.

The scalar collisional invariants of the nonreactive collision operator $\mathcal{S}$ form a linear space spanned by $\psi^{l}, l \in\left\{1, \ldots, n^{s}+4\right\}$, with $\psi^{l}=\left(\delta_{l i}\right)_{i \in \mathcal{S}}$, for $l \in \mathcal{S}, \psi^{l}=\left(m_{i} c_{i \nu}\right)_{i \in \mathcal{S}}$, for $l=n^{s}+\nu, \nu=1,2,3$, and $\psi^{l}=\left(\frac{1}{2} m_{i} \boldsymbol{c}_{i} \cdot \boldsymbol{c}_{i}+\mathcal{E}_{i \mathrm{I}}\right)_{i \in \mathcal{S}}$, for $l=n^{s}+4$, where $c_{i \nu}$ is the component of $\boldsymbol{c}_{i}$ in the $\nu$ th spatial coordinate. For two families $\xi=\left(\xi_{i}\right)_{i \in \mathcal{S}}$ and $\zeta=\left(\zeta_{i}\right)_{i \in \mathcal{S}}$, we define the scalar product by

$$
\langle\langle\xi, \zeta\rangle\rangle=\sum_{i, \mathrm{I}} \int \xi_{i} \odot \bar{\zeta}_{i} \mathrm{~d} \boldsymbol{c}_{i}
$$

where $\xi_{i} \odot \bar{\zeta}_{i}$ denotes the maximum contracted product between the tensor $\xi_{i}$ and the complex conjugate tensor $\bar{\zeta}_{i}$. The scalar product is defined for families of complex tensors as such quantities naturally arise in the solution of Boltzmann linearized equations in the presence of magnetic fields.

An approximate solution to the Boltzmann equations (1) is obtained by using Enskog expansion

$$
\begin{equation*}
f_{i}=f_{i}^{0}\left(1+\epsilon \phi_{i}+\mathcal{O}\left(\epsilon^{2}\right)\right), \quad i \in \mathcal{S} \tag{2}
\end{equation*}
$$

where $f^{0}$ yields the same local macroscopic properties as $f$

$$
\begin{equation*}
\left\langle\left\langle f^{0}, \psi^{l}\right\rangle\right\rangle=\left\langle\left\langle f, \psi^{l}\right\rangle\right\rangle, \quad l \in\left\{1, \ldots, n^{s}+4\right\} . \tag{3}
\end{equation*}
$$

The family of zeroth-order species distribution functions $f^{0}=\left(f_{i}^{0}\right)_{i \in \mathcal{S}}$ is shown to be given by generalized Maxwellian distributions [21, 25]

$$
\begin{equation*}
f_{i}^{0}=\frac{n_{i}}{\beta_{i \mathrm{I}} Q_{i}} \exp \left(-\frac{m_{i}}{2 k_{\mathrm{B}} T} \boldsymbol{C}_{i} \cdot \boldsymbol{C}_{i}-\frac{\mathcal{E}_{i \mathrm{I}}}{k_{\mathrm{B}} T}\right), \quad i \in \mathcal{S}, \tag{4}
\end{equation*}
$$

where $n_{i}$ is the number density of the $i$ th species, $k_{\mathrm{B}}$ the Boltzmann constant, $\boldsymbol{C}_{i}=\boldsymbol{c}_{i}-\boldsymbol{v}$ the relative velocity of the $i$ th species, $T$ the temperature, $Q_{i}$ the full partition function per unit volume of the $i$ th species $Q_{i}=Q_{i}^{\text {int }} Q_{i}^{\operatorname{tr}}$ with $Q_{i}^{\text {int }}=\sum_{\mathrm{I}} \alpha_{i \mathrm{I}} \exp \left(-\frac{\mathcal{E}_{i t}}{k_{\mathrm{B}} T}\right)$ and $Q_{i}^{\operatorname{tr}}=\left(\frac{2 \pi m_{i} k_{\mathrm{B}} T}{\mathrm{~h}_{\mathrm{P}}^{2}}\right)^{3 / 2}, \alpha_{i \mathrm{I}}$ the degeneracy of the $i$ th species in the Ith state, $\mathrm{h}_{\mathrm{P}}$ the Planck constant and $\beta_{i \mathrm{I}}=\mathrm{h}_{\mathrm{P}}^{3} / \alpha_{i 1} m_{i}^{3}$.

The macroscopic conservation equations at zeroth order are obtained by taking the scalar product of Boltzmann equations by collisional invariants and by only keeping the zeroth-order terms $\left\langle\left\langle\widetilde{\mathcal{D}}\left(f^{0}\right), \psi^{l}\right\rangle\right\rangle+$ $\left\langle\left\langle\widehat{\mathcal{D}}\left(f^{0} \phi\right), \psi^{l}\right\rangle\right\rangle=0, l \in\left\{1, \ldots, n^{s}+4\right\}$, where $\widetilde{\mathcal{D}}\left(f^{0}\right)=\left(\widetilde{\mathcal{D}}_{i}\left(f_{i}^{0}\right)\right)_{i \in \mathcal{S}}$ and $\widehat{\mathcal{D}}\left(f^{0} \phi\right)=\left(\widehat{\mathcal{D}}_{i}\left(f_{i}^{0} \phi_{i}\right)\right)_{i \in \mathcal{S}}$. These zeroth order equations, together with Maxwell's equations, yield the magnetogasdynamic equations [9, 21, 25].

### 2.2 Linearized Boltzmann equations

The linearized Boltzmann operator, $\mathcal{F}^{\mathcal{S}}=\left(\mathcal{F}_{i}^{\mathcal{S}}\right)_{i \in \mathcal{S}}$, can be written

$$
\begin{equation*}
\mathcal{F}_{i}^{\mathcal{S}}(\phi)=\sum_{j \in \mathcal{S}} \sum_{\mathrm{I}^{\prime} \mathrm{JJ} \mathrm{~J}^{\prime}} \int f_{j}^{0}\left(\phi_{i}+\phi_{j}-\phi_{i}^{\prime}-\phi_{j}^{\prime}\right) \mathrm{W}_{i j}^{\mathrm{IJ} \mathrm{~J}^{\prime} \mathrm{J}^{\prime}} \mathrm{d} \boldsymbol{c}_{j} \mathrm{~d} \boldsymbol{c}_{i}^{\prime} \mathrm{d} \boldsymbol{c}_{j}^{\prime}, \quad i \in \mathcal{S}, \tag{5}
\end{equation*}
$$

where $\phi=\left(\phi_{i}\right)_{i \in \mathcal{S}}$ and $W_{i j}^{\text {IIj' } J^{\prime}}$ is the transition probability between colliding molecules [24, 33]. An important property is that the linearized Boltzmann operator is isotropic, i.e., it converts a tensor constructed from $\left(\boldsymbol{c}_{i}\right)_{i \in \mathcal{S}}$ into another tensor of the same type as in the monatomic case [21]. The bracket operator is defined by $\llbracket \xi, \zeta \rrbracket=\left\langle\left\langle f^{0} \xi, \mathcal{F}^{\mathcal{S}}(\zeta)\right\rangle\right\rangle$, where $\xi=\left(\xi_{i}\right)_{i \in \mathcal{S}}, \zeta=\left(\zeta_{i}\right)_{i \in \mathcal{S}}$, and $\xi_{i}$ and $\zeta_{i}$ depend on $\boldsymbol{c}_{i}$ and I. This bracket operator is hermitian $\llbracket \xi, \zeta \rrbracket=\overline{\llbracket \zeta, \xi \rrbracket}$, positive semi-definite $\llbracket \xi, \xi \rrbracket \geq 0$, and its kernel is spanned by the collisional invariants, that is, $\llbracket \xi, \xi \rrbracket=0$ implies that $\xi$ is a (tensorial) collisional invariants, so that all its tensorial components are scalar collisional invariants.

The first-order integro-differential equations governing $\phi=\left(\phi_{i}\right)_{i \in \mathcal{S}}$ are easily obtained from (1) and written $\mathcal{F}_{i}^{\mathcal{S}}(\phi)=-z_{i}\left(\boldsymbol{C}_{i} \wedge \boldsymbol{B}\right) \cdot \boldsymbol{\partial}_{\boldsymbol{c}_{i}} \phi_{i}-\widetilde{\mathcal{D}}_{i}\left(\log f_{i}^{0}\right), i \in \mathcal{S}$, with the scalar constraints $\left\langle\left\langle f^{0} \phi, \psi^{l}\right\rangle\right\rangle=0$, $l \in\left\{1, \ldots, n^{s}+4\right\}$. By linearity and isotropy of the linearized Boltzmann operator $\mathcal{F}^{\mathcal{S}}$, the solution $\phi=\left(\phi_{i}\right)_{i \in \mathcal{S}}$ is expanded in the form

$$
\begin{equation*}
\phi_{i}=-\boldsymbol{\phi}_{i}^{\eta}: \boldsymbol{\partial}_{\boldsymbol{x}} \boldsymbol{v}-\frac{1}{3} \phi_{i}^{\kappa} \boldsymbol{\partial}_{\boldsymbol{x}} \cdot \boldsymbol{v}-\sum_{j \in \mathcal{S}} \boldsymbol{\phi}_{i}^{D_{j}} \cdot\left(\boldsymbol{\partial}_{\boldsymbol{x}} p_{j}-\rho_{j} \widetilde{\boldsymbol{b}}_{j}\right)-\boldsymbol{\phi}_{i}^{\widehat{\lambda}} \cdot \boldsymbol{\partial}_{\boldsymbol{x}}\left(\frac{1}{k_{\mathrm{B}} T}\right) . \tag{6}
\end{equation*}
$$

After some algebra, the tensorial functionals $\phi^{\mu}$, for $\mu \in\left\{\eta, \kappa,\left(D_{j}\right)_{j \in \mathcal{S}}, \widehat{\lambda}\right\}$, are shown to satisfy the integro-differential equations

$$
\begin{equation*}
\mathcal{F}_{i}^{\mathcal{S}}\left(\phi^{\mu}\right)+z_{i}\left(\boldsymbol{C}_{i} \wedge \boldsymbol{B}\right) \cdot \boldsymbol{\partial}_{\boldsymbol{c}_{i}} \phi_{i}^{\mu}+\sum_{j, \mathrm{~J}} \frac{m_{i} e_{j}}{\rho k_{\mathrm{B}} T} \boldsymbol{C}_{i} \cdot \int f_{j}^{0} \boldsymbol{C}_{j} \wedge \boldsymbol{B} \phi_{j}^{\mu} \mathrm{d} \boldsymbol{c}_{j}=\Psi_{i}^{\mu}, \quad i \in \mathcal{S}, \tag{7}
\end{equation*}
$$

and the scalar constraints

$$
\begin{equation*}
\left\langle\left\langle f^{0} \phi^{\mu}, \psi^{l}\right\rangle\right\rangle=0, \quad l \in\left\{1, \ldots, n^{s}+4\right\} \tag{8}
\end{equation*}
$$

where $\boldsymbol{\Psi}_{i}^{\eta}=\frac{m_{i}}{k_{\mathrm{B}} T}\left(\boldsymbol{C}_{i} \otimes \boldsymbol{C}_{i}-\frac{1}{3} \boldsymbol{C}_{i} \cdot \boldsymbol{C}_{i} \boldsymbol{I}\right), \Psi_{i}^{\kappa}=\frac{2 \mathrm{c}^{\mathrm{int}}}{\boldsymbol{c}_{v} k_{\mathrm{B}} T}\left(\frac{1}{2} m_{i} \boldsymbol{C}_{i} \cdot \boldsymbol{C}_{i}-\frac{3}{2} k_{\mathrm{B}} T\right)+\frac{2 \mathrm{c}_{v}^{\mathrm{tr}}}{\boldsymbol{c}_{v} k_{\mathrm{B}} T}\left(\overline{\mathcal{E}_{i}}-\mathcal{E}_{i \mathrm{I}}\right), \boldsymbol{\Psi}_{i}^{D_{j}}=\frac{1}{p_{i}}\left(\delta_{i j}-\right.$ $\left.\frac{\rho_{i}}{\rho}\right) \boldsymbol{C}_{i}, \boldsymbol{\Psi}_{i}^{\widehat{\lambda}}=\left(\frac{5}{2} k_{\mathrm{B}} T-\frac{1}{2} m_{i} \boldsymbol{C}_{i} \cdot \boldsymbol{C}_{i}+\overline{\mathcal{E}_{i}}-\mathcal{E}_{\mathrm{iI}_{\mathrm{I}}}\right) \boldsymbol{C}_{i}$, for $i \in \mathcal{S}$, where $\boldsymbol{c}_{v}^{\text {tr }}$ is the translational heat capacity per molecule at constant volume, $\mathfrak{c}^{\text {int }}$ the internal heat capacity per molecule of the mixture, $\mathfrak{c}_{v}=\mathfrak{c}_{v}^{\mathrm{tr}}+\mathfrak{c}^{\text {int }}$ the heat capacity at constant volume per molecule of the mixture, $\overline{\mathcal{E}_{i}}=\sum_{\mathrm{I}} \alpha_{i \mathrm{I}} \mathcal{E}_{i_{\mathrm{I}}} \exp \left(-\frac{\mathcal{E}_{i 1}}{k_{\mathrm{B}} T}\right) / Q_{i}^{\text {int }}$ the averaged internal energy per molecule of the $i$ th species, and $p_{i}$ the partial pressure of the $i$ th species.

### 2.3 First-order conservation equations

The macroscopic conservation equations at first-order are obtained by taking the scalar product of Boltzmann equations with collisional invariants and by keeping the zeroth and first order terms $\left\langle\left\langle\widetilde{\mathcal{D}}\left(f^{0}+f^{0} \phi\right), \psi^{l}\right\rangle\right\rangle+\left\langle\left\langle\widehat{\mathcal{D}}\left(f^{0} \phi\right), \psi^{l}\right\rangle\right\rangle=\left\langle\left\langle\mathcal{C}\left(f^{0}\right), \psi^{l}\right\rangle\right\rangle, l \in\left\{1, \ldots, n^{s}+4\right\}$, where we have defined $\mathcal{C}\left(f^{0}\right)=$ $\left(\mathcal{C}_{i}\left(f^{0}\right)\right)_{i \in \mathcal{S}}$. Note that the terms $\left\langle\left\langle\widehat{\mathcal{D}}\left(f^{0} \phi^{(2)}\right), \psi^{l}\right\rangle\right\rangle$ associated with second order currents have been neglected [11, 25].

After some algebra, the species mass conservation equations, obtained for $l=1, \ldots, n^{s}$, are in the form

$$
\begin{equation*}
\partial_{t} \rho_{i}+\boldsymbol{\partial}_{\boldsymbol{x}} \cdot\left(\rho_{i} \boldsymbol{v}\right)+\boldsymbol{\partial}_{\boldsymbol{x}} \cdot\left(\rho_{i} \boldsymbol{V}_{i}\right)=m_{i} \bar{\omega}_{i}^{0}, \quad i \in \mathcal{S} \tag{9}
\end{equation*}
$$

where $\boldsymbol{V}_{i}=\frac{1}{n_{i}} \sum_{\mathrm{I}} \int \boldsymbol{C}_{i} f_{i}^{0} \phi_{i} \mathrm{~d} \boldsymbol{c}_{i}$ is the diffusion velocities and $\bar{\omega}_{i}^{0}=\sum_{\mathrm{I}} \int \mathcal{C}_{i}\left(f^{0}\right) \mathrm{d} \boldsymbol{c}_{i}$ the chemical source term of the $i$ th species discussed in [24]. The momentum conservation equation, obtained from $l=$ $n^{s}+1, n^{s}+2$, and $n^{s}+3$, reads

$$
\begin{equation*}
\partial_{t}(\rho \boldsymbol{v})+\boldsymbol{\partial}_{\boldsymbol{x}} \cdot(\rho \boldsymbol{v} \otimes \boldsymbol{v}+p \boldsymbol{I})+\boldsymbol{\partial}_{\boldsymbol{x}} \cdot \boldsymbol{\Pi}=\rho \boldsymbol{g}+\mathcal{Q}(\boldsymbol{E}+\boldsymbol{v} \wedge \boldsymbol{B})+\boldsymbol{j} \wedge \boldsymbol{B} \tag{10}
\end{equation*}
$$

where $\mathcal{Q}=\sum_{i \in \mathcal{S}} n_{i} e_{i}$ is the total charge per unit volume, $\boldsymbol{j}=\sum_{i \in \mathcal{S}} n_{i} e_{i} \boldsymbol{V}_{i}$ the conduction current and $\boldsymbol{\Pi}=\sum_{i, \mathrm{I}} \int m_{i} \boldsymbol{C}_{i} \otimes \boldsymbol{C}_{i} f_{i}^{0} \phi_{i} \mathrm{~d} \boldsymbol{c}_{i}$ the viscous tensor. The energy conservation equation, obtained for $l=n^{s}+4$, finally reads

$$
\begin{align*}
\partial_{t}\left(\frac{1}{2} \rho \boldsymbol{v} \cdot \boldsymbol{v}+\mathcal{E}\right)+\boldsymbol{\partial}_{\boldsymbol{x}} \cdot\left(\left(\frac{1}{2} \rho \boldsymbol{v} \cdot \boldsymbol{v}+\mathcal{E}+p\right) \boldsymbol{v}\right) \quad & +\boldsymbol{\partial}_{\boldsymbol{x}} \cdot(\boldsymbol{q}+\boldsymbol{\Pi} \cdot \boldsymbol{v})= \\
& (\rho \boldsymbol{g}+\mathcal{Q}(\boldsymbol{E}+\boldsymbol{v} \wedge \boldsymbol{B})) \cdot \boldsymbol{v}+\boldsymbol{j} \cdot \boldsymbol{E} \tag{11}
\end{align*}
$$

where $\boldsymbol{q}=\sum_{i, \mathrm{I}} \int\left(\frac{1}{2} m_{i} \boldsymbol{C}_{i} \cdot \boldsymbol{C}_{i}+\mathcal{E}_{i \mathrm{I}}\right) \boldsymbol{c}_{i} f_{i}^{0} \phi_{i} \mathrm{~d} \boldsymbol{c}_{i}$ is the heat flux vector.

## 3 The shear viscosities

### 3.1 A new expansion for $\phi^{\eta}$

The solution $\phi^{\eta}=\left(\phi_{i}^{\eta}\right)_{i \in \mathcal{S}}$ of $(7)(8)$ with $\mu=\eta$ is such that $\phi_{i}^{\eta}$ is composed from all symmetric traceless second-order tensors created from the vector $\mathcal{C}_{i}=\sqrt{m_{i} / 2 k_{\mathrm{B}} T} \boldsymbol{C}_{i}$ and the pseudo-vector $\boldsymbol{B}$ which form a space of dimension five [39]. In this paper, we introduce the new tensor expansion

$$
\begin{equation*}
\phi_{i}^{\eta}=\phi_{i}^{\eta(1)} \mathbf{T}_{i}^{(1)}+\phi_{i}^{\eta(2)} \mathbf{T}_{i}^{(2)}+\phi_{i}^{\eta(3)} \mathbf{T}_{i}^{(3)}+\phi_{i}^{\eta(4)} \mathbf{T}_{i}^{(4)}+\phi_{i}^{\eta(5)} \mathbf{T}_{i}^{(5)} \tag{12}
\end{equation*}
$$

where $\phi_{i}^{\eta(I)}, \mathrm{I}=1, \ldots, 5$, are scalar functions of $\mathcal{C}_{i} \cdot \mathcal{C}_{i},\left(\mathcal{C}_{i} \cdot \boldsymbol{B}\right)^{2}$ and $\boldsymbol{B} \cdot \boldsymbol{B}$, for $i \in \mathcal{S}$, in terms of the five independent tensors $\mathbf{T}_{i}^{(1)}, \ldots, \mathbf{T}_{i}^{(5)}$, defined by

$$
\begin{aligned}
\mathbf{T}_{i}^{(1)} & =\mathcal{C}_{i} \otimes \mathcal{C}_{i}-\frac{1}{3} \mathcal{C}_{i} \cdot \mathcal{C}_{i} \boldsymbol{I}, \\
\mathbf{T}_{i}^{(2)} & =\frac{1}{2}\left[\mathcal{C}_{i} \otimes\left(\mathcal{C}_{i} \wedge \boldsymbol{B}\right)+\left(\mathcal{C}_{i} \wedge \boldsymbol{B}\right) \otimes \mathcal{C}_{i}\right] \\
\mathbf{T}_{i}^{(3)} & =\left(\mathcal{C}_{i} \wedge \boldsymbol{B}\right) \otimes\left(\mathcal{C}_{i} \wedge \boldsymbol{B}\right)-\frac{1}{3} \mathcal{C}_{i} \cdot \mathcal{C}_{i} \boldsymbol{B} \cdot \boldsymbol{B} \boldsymbol{I}+\left(\mathcal{C}_{i} \cdot \boldsymbol{B}\right)^{2} \boldsymbol{B} \otimes \boldsymbol{B} / \boldsymbol{B} \cdot \boldsymbol{B} \\
\mathbf{T}_{i}^{(4)} & =\frac{1}{2} \mathcal{C}_{i} \cdot \boldsymbol{B}\left[\mathcal{C}_{i} \otimes \boldsymbol{B}+\boldsymbol{B} \otimes \mathcal{C}_{i}\right]-\left(\mathcal{C}_{i} \cdot \boldsymbol{B}\right)^{2} \boldsymbol{B} \otimes \boldsymbol{B} / \boldsymbol{B} \cdot \boldsymbol{B}, \\
\mathbf{T}_{i}^{(5)} & =\frac{1}{2} \mathcal{C}_{i} \cdot \boldsymbol{B}\left[\boldsymbol{B} \otimes\left(\mathcal{C}_{i} \wedge \boldsymbol{B}\right)+\left(\mathcal{C}_{i} \wedge \boldsymbol{B}\right) \otimes \boldsymbol{B}\right] .
\end{aligned}
$$

The former generating family of six tensors $\mathbf{T}_{i}^{[1]}, \ldots, \mathbf{T}_{i}^{[6]}$ is related to the new basis by $\mathbf{T}_{i}^{[1]}=\mathbf{T}_{i}^{(1)}$, $\mathbf{T}_{i}^{[2]}=\mathbf{T}_{i}^{(2)}, \mathbf{T}_{i}^{[5]}=\mathbf{T}_{i}^{(5)}, \mathbf{T}_{i}^{[6]}=\frac{\left(\mathcal{C}_{i} \cdot \boldsymbol{B}\right)^{2} \boldsymbol{B} \cdot \boldsymbol{B}}{\boldsymbol{\mathcal { C }}_{i} \cdot \mathcal{C}_{i} \boldsymbol{B} \cdot \boldsymbol{B}-3\left(\boldsymbol{C}_{i} \cdot \boldsymbol{B}\right)^{2}}\left(2 \mathbf{T}_{i}^{(4)}-\mathbf{T}_{i}^{(3)}-\boldsymbol{B} \cdot \boldsymbol{B} \mathbf{T}_{i}^{(1)}\right), \mathbf{T}_{i}^{[3]}=\mathbf{T}_{i}^{(3)}-\frac{1}{\boldsymbol{B} \cdot \boldsymbol{B}} \mathbf{T}_{i}^{[6]}$, $\mathbf{T}_{i}^{[4]}=\mathbf{T}_{i}^{(4)}+\frac{1}{\boldsymbol{B} \cdot \boldsymbol{B}} \mathbf{T}_{i}^{[6]}$. These six tensors are linearly dependent and the linear relation $\mathcal{C}_{i} \cdot \mathcal{C}_{i} \mathbf{T}_{i}^{[6]}+$ $\left(\boldsymbol{\mathcal { C }}_{i} \cdot \boldsymbol{B}\right)^{2}\left[\mathbf{T}_{i}^{[3]}+\boldsymbol{B} \cdot \boldsymbol{B} \mathbf{T}_{i}^{[1]}-2 \mathbf{T}_{i}^{[4]}\right]=0$ holds [21]. After some algebra, it is established that the former expansion $\phi_{i}^{\eta}=\sum_{l=1}^{6} \phi_{i}^{\eta[1]} \mathbf{T}_{i}^{[1]}$ and the new one are equally valid and that $\phi_{i}^{\eta(1)}=\phi_{i}^{\eta[1]}, i \in \mathcal{S}, I \in$ $\{1, \ldots, 5\}$.

### 3.2 Properties of the new tensor basis

Substituting expansion (12) into equation (7) for $\mu=\eta$, using the isotropy of the Boltzmann linearized operator $\mathcal{F}^{\mathcal{S}}$, and equating the corresponding terms, yield five equations, each one involving one tensor $\mathbf{T}_{i}^{(1)}$ for $I=1, \ldots, 5$. An important properties of the new tensors, however, is that they are simple linear transformations of the tensor $\mathbf{T}_{i}^{(1)}=\mathcal{C}_{i} \otimes \mathcal{C}_{i}-\frac{1}{3} \mathcal{C}_{i} \cdot \mathcal{C}_{i} \boldsymbol{I}$ with coefficients independent of the particle velocities $\mathcal{C}_{i}, i \in \mathcal{S}$

$$
\begin{align*}
\mathbf{T}_{i}^{(2)} & =\frac{1}{2}\left(\mathbf{T}_{i}^{(1)} \boldsymbol{R}(\boldsymbol{B})-\boldsymbol{R}(\boldsymbol{B}) \mathbf{T}_{i}^{(1)}\right),  \tag{13}\\
\mathbf{T}_{i}^{(3)} & =-\boldsymbol{R}(\boldsymbol{B}) \mathbf{T}_{i}^{(1)} \boldsymbol{R}(\boldsymbol{B})+\frac{1}{\boldsymbol{B} \cdot \boldsymbol{B}} \boldsymbol{B} \otimes \boldsymbol{B} \mathbf{T}_{i}^{(1)} \boldsymbol{B} \otimes \boldsymbol{B}  \tag{14}\\
\mathbf{T}_{i}^{(4)} & =\frac{1}{2}\left(\mathbf{T}_{i}^{(1)} \boldsymbol{R}(\boldsymbol{B})+\boldsymbol{R}(\boldsymbol{B}) \mathbf{T}_{i}^{(1)}\right)-\frac{1}{\boldsymbol{B} \cdot \boldsymbol{B}} \boldsymbol{B} \otimes \boldsymbol{B} \mathbf{T}_{i}^{(1)} \boldsymbol{B} \otimes \boldsymbol{B}  \tag{15}\\
\mathbf{T}_{i}^{(5)} & =\frac{1}{2}\left(\boldsymbol{B} \otimes \boldsymbol{B} \mathbf{T}_{i}^{(1)} \boldsymbol{R}(\boldsymbol{B})-\boldsymbol{R}(\boldsymbol{B}) \mathbf{T}_{i}^{(1)} \boldsymbol{B} \otimes \boldsymbol{B}\right) \tag{16}
\end{align*}
$$

where $\boldsymbol{B} \otimes \boldsymbol{B}$ denotes the tensor product of the magnetic field $\boldsymbol{B}$ with itself and $\boldsymbol{R}(\boldsymbol{B})$ the rotation matrix associated with $\boldsymbol{B}$. For any vector $\mathbf{Z}$, the rotation matrix $\boldsymbol{R}(\mathbf{Z})$ is defined by

$$
\boldsymbol{R}(\boldsymbol{Z})=\left(\begin{array}{ccc}
0 & -Z_{3} & Z_{2} \\
Z_{3} & 0 & -Z_{1} \\
-Z_{2} & Z_{1} & 0
\end{array}\right)
$$

Using these relations and the linear equations associated with each tensor $\mathbf{T}_{i}^{(1)}$ we naturally obtain five coupled equations between the family of tensors $\phi^{\eta(I)}=\left(\phi_{i}^{\eta(I)}\right)_{i \in \mathcal{S}}$ defined for $I=1, \ldots, 5$, by

$$
\phi_{i}^{\eta(I)}=\phi_{i}^{\eta(I)}\left(\mathcal{C}_{i} \otimes \mathcal{C}_{i}-\frac{1}{3} \mathcal{C}_{i} \cdot \mathcal{C}_{i} \boldsymbol{I}\right), \quad i \in \mathcal{S}
$$

The resulting equations are in the form

$$
\begin{align*}
& \mathcal{F}_{i}^{\mathcal{S}}\left(\phi^{\eta(1)}\right)-z_{i} B^{2} \boldsymbol{\phi}_{i}^{\eta(2)}=\mathbf{\Psi}_{i}^{\eta}, \quad i \in \mathcal{S},  \tag{17}\\
& \mathcal{F}_{i}^{\mathcal{S}}\left(\phi^{\eta(2)}\right)+2 z_{i}\left(\boldsymbol{\phi}_{i}^{\eta(1)}-B^{2} \boldsymbol{\phi}_{i}^{\eta(3)}\right)=0, \quad i \in \mathcal{S},  \tag{18}\\
& \mathcal{F}_{i}^{\mathcal{S}}\left(\phi^{\eta(3)}\right)+z_{i} \boldsymbol{\phi}_{i}^{\eta(2)}=0, \quad i \in \mathcal{S},  \tag{19}\\
& \mathcal{F}_{i}^{\mathcal{S}}\left(\phi^{\eta(4)}\right)+z_{i}\left(\phi_{i}^{\eta(2)}-B^{2} \phi_{i}^{\eta(5)}\right)=0, \quad i \in \mathcal{S},  \tag{20}\\
& \mathcal{F}_{i}^{\mathcal{S}}\left(\phi^{\eta(5)}\right)+z_{i}\left(2 \boldsymbol{\phi}_{i}^{\eta(3)}+\phi_{i}^{\eta(4)}\right)=0, \quad i \in \mathcal{S}, \tag{21}
\end{align*}
$$

and the derivation of (17)-(21) is clear and direct at variance with the case of the former generating family where the derivation of similar equations was somewhat obscure mainly because of the dependence on particle velocities of the proportionality coefficients between $\mathbf{T}_{i}^{[3]}, \mathbf{T}_{i}^{[4]}, \mathbf{T}_{i}^{[6]}$, and $\mathbf{T}_{i}^{[1]}$. Upon introducing the usual auxiliary complex quantities

$$
\begin{aligned}
\boldsymbol{\varphi}_{i}^{\eta(1)} & =\boldsymbol{\phi}_{i}^{\eta(1)}+B^{2} \boldsymbol{\phi}_{i}^{\eta(3)} \\
\boldsymbol{\varphi}_{i}^{\eta(2)} & =\phi_{i}^{\eta(1)}+\mathrm{i} B \boldsymbol{\phi}_{i}^{\eta(2)}-B^{2} \boldsymbol{\phi}_{i}^{(3)}, \\
\boldsymbol{\varphi}_{i}^{\eta(3)} & =\boldsymbol{\phi}_{i}^{\eta(1)}+\frac{1}{2} \mathrm{i} B \boldsymbol{\phi}_{i}^{\eta(2)}+\frac{1}{2} B^{2} \boldsymbol{\phi}_{i}^{\eta(4)}+\frac{1}{2} \mathrm{i} B^{3} \boldsymbol{\phi}_{i}^{\eta(5)},
\end{aligned}
$$

where $\mathrm{i}^{2}=-1$, we recover the integral equations

$$
\begin{equation*}
\mathcal{F}^{\mathcal{S}}\left(\boldsymbol{\varphi}^{\eta(1)}\right)=\boldsymbol{\Psi}^{\eta}, \quad\left(\mathcal{F}^{\mathcal{S}}+2 \mathrm{i} B \mathcal{F}^{z, m}\right)\left(\boldsymbol{\varphi}^{\eta(2)}\right)=\boldsymbol{\Psi}^{\eta}, \quad\left(\mathcal{F}^{\mathcal{S}}+\mathrm{i} B \mathcal{F}^{z, m}\right)\left(\boldsymbol{\varphi}^{\eta(3)}\right)=\boldsymbol{\Psi}^{\eta} \tag{22}
\end{equation*}
$$

and the scalar constraints are automatically satisfied. Note that this was not the case for the former tensor expansion since $\mathbf{T}_{i}^{[3]}, \mathbf{T}_{i}^{[4]}$, and $\mathbf{T}_{i}^{[6]}$ are not orthogonal to collisional invariant and the constraint $\boldsymbol{B} \cdot \boldsymbol{B} \phi_{i}^{\eta[6]}=\phi_{i}^{\eta[3]}-\phi_{i}^{\eta[4]}$ was needed among the former expansion coefficients. The operator $\mathcal{F}^{z, m}=$ $\left(\mathcal{F}_{i}^{z, m}\right)_{i \in \mathcal{S}}$ is defined for $\mathbf{u}=\left(\mathbf{u}_{i}\right)_{i \in \mathcal{S}}$ by $\mathcal{F}_{i}^{z, m}(\mathbf{u})=z_{i} \mathbf{u}_{i}, i \in \mathcal{S}$, where $\mathbf{u}_{i}$ is the product of $\mathcal{C}_{i} \otimes \mathcal{C}_{i}-$ $\frac{1}{3} \mathcal{C}_{i} \cdot \mathcal{C}_{i} \boldsymbol{I}$ by a complex scalar function of $\boldsymbol{C}_{i} \cdot \boldsymbol{C}_{i},\left(\boldsymbol{C}_{i} \cdot \boldsymbol{B}\right)^{2}$ and $\boldsymbol{B} \cdot \boldsymbol{B}$. These systems are shown to be well posed [25] and imply that the scalar function $\varphi_{i}^{\eta(1)}$ such that $\boldsymbol{\varphi}_{i}^{\eta(1)}=\varphi_{i}^{\eta(1)}\left(\mathcal{C}_{i} \otimes \mathcal{C}_{i}-\frac{1}{3} \mathcal{C}_{i} \cdot \mathcal{C}_{i} \boldsymbol{I}\right)$ only depends on $\boldsymbol{C}_{i} \cdot \boldsymbol{C}_{i}$ and $\boldsymbol{B} \cdot \boldsymbol{B}$, for $\mathrm{I} \in\{1,2,3\}[21]$.

### 3.3 Expressions of the viscous stress tensor $\Pi$

From the relation $\boldsymbol{\Pi}=k_{\mathrm{B}} T\left\langle\left\langle\boldsymbol{\Psi}^{\eta}, f^{0} \phi\right\rangle\right\rangle+\frac{1}{3} k_{\mathrm{B}} T\left\langle\left\langle\Psi^{\kappa}, f^{0} \phi\right\rangle\right\rangle \boldsymbol{I}$ and the expansion of $\phi$ it is obtained that

$$
\begin{align*}
& -\boldsymbol{\Pi}=\kappa\left(\boldsymbol{\partial}_{\boldsymbol{x}} \cdot \boldsymbol{v}\right) \boldsymbol{I}+\eta_{1} \mathbf{S}+\eta_{2}(\boldsymbol{R}(\mathcal{B}) \mathbf{S}-\mathbf{S} \boldsymbol{R}(\mathcal{B}))+\eta_{3}\left(\mathcal{B}^{t} \mathbf{S B} \mathcal{B} \otimes \mathcal{B}-\boldsymbol{R}(\mathcal{B}) \mathbf{S} \boldsymbol{R}(\mathcal{B})\right) \\
& +\eta_{4}\left(\mathbf{S} \mathcal{B} \otimes \mathcal{B}+\mathcal{B} \otimes \mathcal{B} \mathbf{S}-2 \mathcal{B}^{t} \mathbf{S B} \mathcal{B} \otimes \mathcal{B}\right)+\eta_{5}(\mathcal{B} \otimes \mathcal{B} \mathbf{S} \boldsymbol{R}(\mathcal{B})-\boldsymbol{R}(\mathcal{B}) \mathbf{S} \mathcal{B} \otimes \mathcal{B}) \tag{23}
\end{align*}
$$

where $\mathbf{S}=\boldsymbol{\partial}_{\boldsymbol{x}} \boldsymbol{v}+\boldsymbol{\partial}_{\boldsymbol{x}} \boldsymbol{v}^{t}-\frac{2}{3}\left(\boldsymbol{\partial}_{\boldsymbol{x}} \cdot \boldsymbol{v}\right) \boldsymbol{I}, \kappa=\frac{1}{9} k_{\boldsymbol{B}} T \llbracket \phi^{\kappa}, \phi^{\kappa} \rrbracket$ and the five shear viscosities $\eta_{1}, \ldots, \eta_{5}$ are given by

$$
\begin{align*}
& \eta_{1}=\frac{1}{20} k_{\mathrm{B}} T\left(\llbracket \boldsymbol{\varphi}^{\eta(1)}, \boldsymbol{\varphi}^{\eta(1)} \rrbracket+\llbracket \boldsymbol{\varphi}^{\eta(2)}, \boldsymbol{\varphi}^{\eta(2)} \rrbracket\right),  \tag{24}\\
& \eta_{2}=-\frac{1}{10} k_{\mathrm{B}} T\left(\left(\boldsymbol{\varphi}^{\eta(2)}, \boldsymbol{\varphi}^{\eta(2)}\right)\right)  \tag{25}\\
& \eta_{3}=\frac{1}{20} k_{\mathrm{B}} T\left(\llbracket \boldsymbol{\varphi}^{\eta(1)}, \boldsymbol{\varphi}^{\eta(1)} \rrbracket-\llbracket \boldsymbol{\varphi}^{\eta(2)}, \boldsymbol{\varphi}^{\eta(2)} \rrbracket\right),  \tag{26}\\
& \eta_{4}=\frac{1}{10} k_{\mathrm{B}} T\left(\llbracket \boldsymbol{\varphi}^{\eta(3)}, \boldsymbol{\varphi}^{\eta(3)} \rrbracket-\frac{1}{2} \llbracket \boldsymbol{\varphi}^{\eta(1)}, \boldsymbol{\varphi}^{\eta(1)} \rrbracket-\frac{1}{2} \llbracket \boldsymbol{\varphi}^{\eta(2)}, \boldsymbol{\varphi}^{\eta(2)} \rrbracket\right),  \tag{27}\\
& \eta_{5}=\frac{1}{10} k_{\mathrm{B}} T\left(\left(\left(\boldsymbol{\varphi}^{\eta(2)}, \boldsymbol{\varphi}^{\eta(2)}\right)\right)-\left(\left(\boldsymbol{\varphi}^{\eta(3)}, \boldsymbol{\varphi}^{\eta(3)}\right)\right)\right), \tag{28}
\end{align*}
$$

where we have defined the scalar product

$$
\begin{equation*}
((\xi, \zeta))=\sum_{k, K} z_{k} B \int f_{k}^{0} \xi_{k} \odot \bar{\zeta}_{k} \mathrm{~d} \boldsymbol{c}_{k} \tag{29}
\end{equation*}
$$

The new tensor basis finally yields identical integral equations and bracket expressions for the five shear viscosities but in a clear and straightforward way. After some algebra, denoting by $\Re(z)$ and $\Im(z)$ the real and imaginary part of a complex quantity $z=\Re(z)+\mathrm{i} \Im(z)$, it is further obtained that

$$
\begin{align*}
& \eta_{1}=\frac{1}{20} k_{\mathrm{B}} T\left(\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\eta(1)}, \boldsymbol{\Psi}^{\eta}\right\rangle\right\rangle+\Re\left(\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\eta(2)}, \boldsymbol{\Psi}^{\eta}\right\rangle\right\rangle\right)\right),  \tag{30}\\
& \eta_{2}=\frac{1}{20} k_{\mathrm{B}} T \Im\left(\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\eta(2)}, \boldsymbol{\Psi}^{\eta}\right\rangle\right\rangle\right),  \tag{31}\\
& \eta_{3}=\frac{1}{20} k_{\mathrm{B}} T\left(\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\eta(1)}, \boldsymbol{\Psi}^{\eta}\right\rangle\right\rangle-\Re\left(\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\eta(2)}, \boldsymbol{\Psi}^{\eta}\right\rangle\right\rangle\right)\right),  \tag{32}\\
& \eta_{4}=\frac{1}{20} k_{\mathrm{B}} T\left(2 \Re\left(\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\eta(3)}, \boldsymbol{\Psi}^{\eta}\right\rangle\right\rangle\right)-\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\eta(1)}, \boldsymbol{\Psi}^{\eta}\right\rangle\right\rangle-\Re\left(\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\eta(2)}, \boldsymbol{\Psi}^{\eta}\right\rangle\right\rangle\right)\right),  \tag{33}\\
& \eta_{5}=\frac{1}{20} k_{\mathrm{B}} T\left(2 \Im\left(\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\eta(3)}, \boldsymbol{\Psi}^{\eta}\right\rangle\right\rangle\right)-\Im\left(\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\eta(2)}, \boldsymbol{\Psi}^{\eta}\right\rangle\right\rangle\right)\right) . \tag{34}
\end{align*}
$$

These new linear relations between the viscosity coefficients and the solutions of the linearized Boltzmann equations will be used to evaluate the shear viscosities from Galerkin approximate solutions. Finally note that the volume viscosity is not influenced by the magnetic field and its evaluation is already discussed in [14, 25].

### 3.4 Expansion polynomials

The integral equations (22) are typically solved by a (hermitian) Galerkin procedure where the perturbed distribution functions are expanded into polynomials. We will use the traditional basis polynomials $\phi^{a 0 c d k}$ defined by

$$
\phi^{a 0 c d k}\left(\boldsymbol{c}_{k}, K\right)=\left(S_{a+\frac{1}{2}}^{c}\left(\boldsymbol{w}_{k} \cdot \boldsymbol{w}_{k}\right) W_{k}^{d}\left(\epsilon_{k K}\right) \overline{\otimes^{a} \boldsymbol{w}_{k}} \delta_{k i}\right)_{i \in \mathcal{S}}
$$

where $\boldsymbol{w}_{k}=\sqrt{m_{k} / 2 k_{\mathrm{B}} T}\left(\boldsymbol{c}_{k}-\boldsymbol{v}\right)$ is the reduced relative velocity of the molecules of the $k$ th species and $\epsilon_{k K}=\mathcal{E}_{k \mathrm{~K}} / k_{\mathrm{B}} T$ is the reduced internal energy of the $k$ th species in the Kth state. In addition, $a, c$,
and $d$ are integers, $S_{a+1 / 2}^{c}$ is the Laguerre and Sonine polynomial of order $c$ with parameter $a+1 / 2$, $W_{k}^{d}$ is the Wang Chang and Uhlenbeck polynomial of order $d$ for the $k$ th species, and $\overline{\otimes^{a} \boldsymbol{w}_{k}}$ is a tensor of rank $a$ with respect to the three-dimensional space, given by $\overline{\otimes^{0} \boldsymbol{w}_{k}}=1, \overline{\otimes^{1} \boldsymbol{w}_{k}}=\boldsymbol{w}_{k}$, and $\overline{\otimes^{2} \boldsymbol{w}_{k}}=\boldsymbol{w}_{k} \otimes \boldsymbol{w}_{k}-\frac{1}{3} \boldsymbol{w}_{k} \cdot \boldsymbol{w}_{k} \boldsymbol{I}[38,34,14]$. In the notation $\phi^{a b c d k}$, the first index $a$ thus refers to the tensorial rank with respect to $\mathbb{R}^{3}$, the second index $b=0$ refers to the absence of polarization effects [14], the third index $c$ refers to the Laguerre and Sonine polynomial, the fourth index $d$ refers to the Wang Chang and Uhlenbeck polynomial, and the last index $k$ refers to the species. These functions have important orthogonality properties [38,34] and various properties of the Laguerre and Sonine polynomials, Wang Chang and Uhlenbeck polynomials, and functions $\phi^{a 0 c d k}$ are summarized in $[21,34,14]$.

### 3.5 Transport linear systems associated with the shear viscosities

The traceless matrix integral equations associated with the shear viscosities are in the form $\left(\mathcal{F}^{\mathcal{S}}+\right.$ $\left.\left(2 \delta_{2 \mid}+\delta_{31}\right) \mathrm{i} B \mathcal{F}^{z, m}\right)\left(\boldsymbol{\varphi}^{\eta(I)}\right)=\boldsymbol{\Psi}^{\eta}, I \in\{1,2,3\}$, where $\boldsymbol{\Psi}^{\eta}=2 \sum_{k \in \mathcal{S}} \phi^{2000 k}$, and $\phi^{2000 k}=\left(\left(\boldsymbol{w}_{k} \otimes \boldsymbol{w}_{k}-\right.\right.$ $\left.\left.\frac{1}{3} \boldsymbol{w}_{k} \cdot \boldsymbol{w}_{k} \boldsymbol{I}\right) \delta_{k i}\right)_{i \in \mathcal{S}}[14]$. By isotropy, the variational approximation space $\mathcal{A}^{\eta}$ to be considered in the first place is the space spanned by $\phi^{2000 k}, k \in \mathcal{S}[9,14,21,38]$. The simulations by Bruno and coworkers have shown that the corresponding coefficients are sufficiently accurate so that higher order expansions of $\varphi^{\eta(I)}, \mathrm{I} \in\{1,2,3\}$ are not required $[6,7]$. A (hermitian) Galerkin approach is used by requiring the difference between the approximated $\left(\mathcal{F}^{\mathcal{S}}+\left(2 \delta_{21}+\delta_{31}\right) \mathrm{i} B \mathcal{F}^{z, m}\right)\left(\boldsymbol{\varphi}^{\eta(\mathrm{I})}\right)$ and $\boldsymbol{\Psi}^{\eta}$ to be orthogonal to the approximation space.

For convenience $\varphi^{\eta(1)}$ is taken in the form

$$
\boldsymbol{\varphi}^{\eta(\mathrm{I})}=(2 / p) \sum_{k \in \mathcal{S}} \alpha_{k}^{\eta(\mathrm{I})} \phi^{2000 k}, \quad \mathrm{I} \in\{1,2,3\} .
$$

The matrix associated with the variational procedure is denoted by $H$ and is rescaled such that $H_{k l}=$ $(2 / 5 n p) \llbracket \phi^{2000 k}, \phi^{2000 l} \rrbracket, k, l \in \mathcal{S}$, where $n$ denotes the mixture number density. We also rescale the right member $\beta_{k}^{\eta}=(1 / 5 n)\left\langle\left\langle f^{0} \phi^{2000 k}, \mathbf{\Psi}^{\eta}\right\rangle\right\rangle, k \in \mathcal{S}$. We then have $H \in \mathbb{R}^{n, n}, \beta^{\eta} \in \mathbb{R}^{n}$, and the linear system for $\alpha^{\eta(1)} \in \mathbb{R}^{n}$ and $\alpha^{\eta(2)}, \alpha^{\eta(3)} \in \mathbb{C}^{n}$ are in the form

$$
\begin{equation*}
H \alpha^{\eta(1)}=X, \quad\left(H+2 \mathrm{i} H^{B}\right) \alpha^{\eta(2)}=X, \quad\left(H+\mathrm{i} H^{B}\right) \alpha^{\eta(3)}=X \tag{35}
\end{equation*}
$$

where $X=\left(X_{1}, \ldots, X_{n}\right)^{t}$ and $X_{k}$ is the mole fraction of the $k$ th species. The coefficients of the matrix $H$ are given by [14]

$$
\begin{align*}
H_{k k} & =\sum_{\substack{l \in \mathcal{S} \\
l \neq k}} \frac{16}{5 k_{\mathrm{B}} T} \frac{X_{k} X_{l} m_{l}^{2}}{\left(m_{k}+m_{l}\right)^{2}}\left[\frac{10}{3} \frac{m_{k}}{m_{l}} \Omega_{k l}^{(1,1)}+\Omega_{k l}^{(2,2)}\right]+\frac{8}{5 k_{\mathrm{B}} T} X_{k}^{2} \Omega_{k k}^{(2,2)}, \quad k \in \mathcal{S}  \tag{36}\\
H_{k l} & =\frac{16}{5 k_{\mathrm{B}} T} \frac{X_{k} X_{l} m_{k} m_{l}}{\left(m_{k}+m_{l}\right)^{2}}\left[-\frac{10}{3} \Omega_{k l}^{(1,1)}+\Omega_{k l}^{(2,2)}\right], \quad k, l \in \mathcal{S}, \quad k \neq l, \tag{37}
\end{align*}
$$

where the $\Omega_{k l}^{(i, j)}$ are the classical collision integrals $[9,21,34]$ and $H^{B}$ is the diagonal matrix $H_{k l}^{B}=$ $\delta_{k l} B X_{k} z_{k} / p, k, l \in \mathcal{S}$.

The matrix $H$ is symmetric positive definite [14] and from (30)-(34) the shear viscosities are finally given by the scalar products

$$
\begin{align*}
& \eta_{1}=\frac{1}{2}\left\langle\alpha^{\eta(1)}, X\right\rangle+\frac{1}{2} \Re\left(\left\langle\alpha^{\eta(2)}, X\right\rangle\right),  \tag{38}\\
& \eta_{2}=\frac{1}{2} \Im\left(\left\langle\alpha^{\eta(2)}, X\right\rangle\right),  \tag{39}\\
& \eta_{3}=\frac{1}{2}\left\langle\alpha^{\eta(1)}, X\right\rangle-\frac{1}{2} \Re\left(\left\langle\alpha^{\eta(2)}, X\right\rangle\right),  \tag{40}\\
& \eta_{4}=\Re\left(\left\langle\alpha^{\eta(3)}, X\right\rangle\right)-\frac{1}{2}\left\langle\alpha^{\eta(1)}, X\right\rangle-\frac{1}{2} \Re\left(\left\langle\alpha^{\eta(2)}, X\right\rangle\right),  \tag{41}\\
& \eta_{5}=\Im\left(\left\langle\alpha^{\eta(3)}, X\right\rangle\right)-\frac{1}{2} \Im\left(\left\langle\alpha^{\eta(2)}, X\right\rangle\right), \tag{42}
\end{align*}
$$

where we have denoted by $\langle x, y\rangle=\sum_{k \in \mathcal{S}} x_{k} \bar{y}_{k}$ the Hermitian scalar product.
In the situation of nonionized and nonmagnetized mixtures, it has been shown that one step of the conjugate gradient algorithm—preconditioned by the diagonal-already yields excellent accuracy for
the shear viscosity $[14,16]$, much better than the Wilke formula. In the situation of ionized magnetized mixtures, however, it is not anymore possible to use strictly speaking a conjugate gradient technique since in general there does not exist short recurrence iterative algorithms which simultaneously corresponds to a global minimization of some error norm over the corresponding Krylov subspaces spanned by the successive residual error vectors [19]. Nevertheless, it is possible to introduce orthogonal error techniques which guarantee that the successive residual error vectors are orthogonal [20, 22, 27]. These techniques are especially suited to the linear systems arising from the Galerkin procedure since it has been shown that - with a proper formulation - such systems are symmetric complex with a positive semi-definite real part and for such systems orthogonal errors algorithms are proved to be convergent $[25,27]$. It is also more efficient to solve such systems by iterative techniques in their complex form rather than in their equivalent real form [22].

Numerical test have been conducted with weakly ionized air at temperature 10000 K and pressure $p=1 \mathrm{~atm}$ with collision integrals taken from [40] and thermodynamic properties taken from [30]. The species associated with ionized air are the $n^{s}=11$ species $\mathrm{N}_{2}, \mathrm{O}_{2}, \mathrm{NO}, \mathrm{N}, \mathrm{O}, \mathrm{N}_{2}^{+}, \mathrm{O}_{2}^{+}, \mathrm{NO}^{+}, \mathrm{N}^{+}, \mathrm{O}^{+}$ and $E^{-}$. The choice of a particular temperature or pressure for weakly ionized air is not significant since convergence properties would essentially be similar at other temperatures or pressures. The numerical tests have first shown that the transport linear systems for ionized mixtures are usually more difficult to solve than that for neutral species because of the greater disparity between collision integrals. Nevertheless, the simulations have indicated that orthogonal error methods preconditioned by the diagonal yield efficient algorithms which converge in a few iterates whatever the intensity of the magnetic field. Relative errors of the order of $10^{-3}$ are typically obtained within three iterations. Finally, as already shown by Bruno and coworkers for ionized Argon, the extra viscosities $\eta_{j}, j=$ $2,3,4,5$ are generally much smaller than $\eta_{1}$ even for large values of the electron Hall parameter [7].

## 4 Mass and heat transport coefficients

### 4.1 Equations associated with $\phi^{\widehat{\lambda}}$

The solution $\phi^{\widehat{\lambda}}=\left(\phi_{i}^{\widehat{\lambda}}\right)_{i \in \mathcal{S}}$ of (7)(8) with $\mu=\widehat{\lambda}$ is in the form

$$
\phi_{i}^{\widehat{\lambda}}=\phi_{i}^{\widehat{\lambda}(1)} \boldsymbol{C}_{i}+\phi_{i}^{\widehat{\lambda}(2)} \boldsymbol{C}_{i} \wedge \boldsymbol{B}+\phi_{i}^{\widehat{\lambda}(3)} \boldsymbol{C}_{i} \cdot \boldsymbol{B} \boldsymbol{B},
$$

where $\phi_{i}^{\widehat{\lambda}(1)}, \phi_{i}^{\widehat{\lambda}(2)}$ and $\phi_{i}^{\widehat{\lambda}(3)}$ are scalar functions of $\boldsymbol{C}_{i} \cdot \boldsymbol{C}_{i},\left(\boldsymbol{C}_{i} \cdot \boldsymbol{B}\right)^{2}$ and $\boldsymbol{B} \cdot \boldsymbol{B}$. Substituting this expansion into the integro-differential equations associated with $\phi^{\widehat{\lambda}}$ and using isotropy first yield three scalar coupled integral equations. Further simplification is then obtained if, for each species $i$, instead of three real quantities $\phi_{i}^{\widehat{\lambda}(1)}, \phi_{i}^{\widehat{\lambda}(2)}$ and $\phi_{i}^{\widehat{\lambda}(3)}$, one real and one complex unknowns are introduced

$$
\varphi_{i}^{\widehat{\lambda}(1)}=\phi_{i}^{\widehat{\lambda}(1)}+B^{2} \phi_{i}^{\widehat{\lambda}(3)}, \quad \varphi_{i}^{\widehat{\lambda}(2)}=\phi_{i}^{\widehat{\lambda}(1)}+\mathrm{i} B \phi_{i}^{\widehat{\lambda}(2)}, \quad i \in \mathcal{S} .
$$

Upon defining $\varphi^{\widehat{\lambda}(1)}=\left(\varphi_{i}^{\widehat{\lambda}(1)} C_{i}\right)_{i \in \mathcal{S}}, \boldsymbol{\varphi}^{\widehat{\lambda}(2)}=\left(\varphi_{i}^{\widehat{\lambda}(2)} \boldsymbol{C}_{i}\right)_{i \in \mathcal{S}}$, and introducing the operator $\mathcal{F}^{z, v}=$ $\left(\mathcal{F}_{i}^{z, v}\right)_{i \in \mathcal{S}}$ defined for $\mathbf{u}=\left(\mathbf{u}_{i}\right)_{i \in \mathcal{S}}$ by

$$
\mathcal{F}_{i}^{z, v}(\mathbf{u})=-m_{i} \boldsymbol{C}_{i} \sum_{j, \mathrm{~s}} \frac{e_{j}}{3 \rho k_{\mathrm{B}} T} \int f_{j}^{0} \mathbf{u}_{j} \cdot \boldsymbol{C}_{j} \mathrm{~d} \boldsymbol{C}_{j}+z_{i} \mathbf{u}_{i}, \quad i \in \mathcal{S},
$$

where $\mathbf{u}_{i}$ is the product of $\boldsymbol{C}_{i}$ by a complex scalar function of $\boldsymbol{C}_{i} \cdot \boldsymbol{C}_{i},\left(\boldsymbol{C}_{i} \cdot \boldsymbol{B}\right)^{2}$ and $\boldsymbol{B} \cdot \boldsymbol{B}$, it is easily shown that

$$
\begin{equation*}
\mathcal{F}^{\mathcal{S}}\left(\boldsymbol{\varphi}^{\widehat{\lambda}(1)}\right)=\boldsymbol{\Psi}^{\widehat{\lambda}}, \quad\left(\mathcal{F}^{\mathcal{S}}+\mathrm{i} B \mathcal{F}^{z, v}\right)\left(\boldsymbol{\varphi}^{\widehat{\lambda}(2)}\right)=\boldsymbol{\Psi}^{\widehat{\lambda}} . \tag{43}
\end{equation*}
$$

Furthermore, the constraint equations (8) are easily rewritten in the form

$$
\begin{equation*}
\left\langle\left\langle f^{0} \varphi^{\widehat{\lambda}(1)}, \psi^{l}\right\rangle\right\rangle=0, \quad\left\langle\left\langle f^{0} \varphi^{\widehat{\lambda}(2)}, \psi^{l}\right\rangle\right\rangle=0, \quad l \in\left\{1, \ldots, n^{s}+4\right\} . \tag{44}
\end{equation*}
$$

The structure of the first integral equation in (43) is classical and the structure of second equation is similar in a complex framework [25]. From the isotropy of the operator $\mathcal{F}^{\mathcal{S}}$ the functions $\varphi^{\widehat{\lambda}(1)}$ and $\varphi^{\widehat{\lambda}(2)}$ cannot be functions of $(\boldsymbol{C} \cdot \boldsymbol{B})^{2}$ [21].

We define the unitary vector $\mathcal{B}$ by $\mathcal{B}=\boldsymbol{B} / B$ and for any vector $\mathbf{X}$, we introduce the associated vectors

$$
\mathbf{X}^{\|}=(\mathbf{X} \cdot \mathcal{B}) \mathcal{B}, \quad \mathbf{X}^{\perp}=\mathbf{X}-\mathbf{X}^{\|}, \quad \mathbf{X}^{\odot}=\mathcal{B} \wedge \mathbf{X}
$$

The vectors $\mathbf{X}^{\|}, \mathbf{X}^{\perp}$ and $\mathbf{X}^{\odot}$ are mutually orthogonal and obtained from $\mathbf{X}$ by applying the linear operators $\mathbf{M}^{\|}=\mathcal{B} \otimes \mathcal{B}, \mathbf{M}^{\perp}=\boldsymbol{I}-\mathcal{B} \otimes \mathcal{B}$ and $\mathbf{M}^{\odot}=\boldsymbol{R}(\mathcal{B})$. It is then straightforward to obtain that

$$
\begin{equation*}
\boldsymbol{\phi}^{\widehat{\lambda}}=\left(\varphi^{\widehat{\lambda}(1)} \mathcal{B} \otimes \mathcal{B}+\Re\left(\varphi^{\widehat{\lambda}(2)}\right)(\boldsymbol{I}-\boldsymbol{\mathcal { B }} \otimes \boldsymbol{B})-\Im\left(\varphi^{\widehat{\lambda}(2)}\right) \boldsymbol{R}(\mathcal{B})\right) \boldsymbol{C}_{i} \tag{45}
\end{equation*}
$$

or equivalently that $\phi^{\widehat{\lambda}}=\Re\left(\varphi^{\widehat{\lambda}(1)} \boldsymbol{C}_{i}^{\|}+\varphi^{\widehat{\lambda}(2)}\left(\boldsymbol{C}_{i}^{\perp}+\mathrm{i} \boldsymbol{C}_{i}^{\odot}\right)\right)$, where $\Re(z)$ and $\Im(z)$ denote the real and imaginary part of a complex quantity $z=\Re(z)+\mathrm{i} \Im(z)$.

### 4.2 Equations associated with $\phi^{D_{j}}$

The above development can be followed through for the solution $\phi^{D_{j}}$ of (7)(8) with $\mu=D_{j}$ as well. More specifically, the perturbed distribution function $\phi^{D_{j}}=\left(\phi_{i}^{D_{j}}\right)_{i \in \mathcal{S}}$ is expanded in the form

$$
\boldsymbol{\phi}_{i}^{D_{j}}=\phi_{i}^{D_{j}(1)} \boldsymbol{C}_{i}+\phi_{i}^{D_{j}(2)} \boldsymbol{C}_{i} \wedge \boldsymbol{B}+\phi_{i}^{D_{j}(3)} \boldsymbol{C}_{i} \cdot \boldsymbol{B} \boldsymbol{B}
$$

and defining $\varphi_{i}^{D_{j}(1)}=\phi_{i}^{D_{j}(1)}+B^{2} \phi_{i}^{D_{j}(3)}, \varphi_{i}^{D_{j}(2)}=\phi_{i}^{D_{j}(1)}+\mathrm{i} B \phi_{i}^{D_{j}(2)}, i, j \in \mathcal{S}$, and $\varphi^{D_{j}(1)}=$ $\left(\varphi_{i}^{D_{j}(1)} C_{i}\right)_{i \in \mathcal{S}}, \varphi^{D_{j}(2)}=\left(\varphi_{i}^{D_{j}(2)} C_{i}\right)_{i \in \mathcal{S}}, j \in \mathcal{S}$, we obtain for all $j \in \mathcal{S}$

$$
\begin{gather*}
\mathcal{F}^{\mathcal{S}}\left(\boldsymbol{\varphi}^{D_{j}(1)}\right)=\boldsymbol{\Psi}^{D_{j}}, \quad\left(\mathcal{F}^{\mathcal{S}}+\mathrm{i} B \mathcal{F}^{z, v}\right)\left(\boldsymbol{\varphi}^{D_{j}(2)}\right)=\boldsymbol{\Psi}^{D_{j}},  \tag{46}\\
\left\langle\left\langle f^{0} \varphi^{D_{j}(1)}, \psi^{l}\right\rangle\right\rangle=0, \quad\left\langle\left\langle f^{0} \varphi^{D_{j}(2)}, \psi^{l}\right\rangle\right\rangle=0, \quad l \in\left\{1, \ldots, n^{s}+4\right\} . \tag{47}
\end{gather*}
$$

We can also write that

$$
\begin{equation*}
\phi^{D_{j}}=\left(\varphi^{D_{j}(1)} \mathcal{B} \otimes \mathcal{B}+\Re\left(\varphi^{D_{j}(2)}\right)(\boldsymbol{I}-\mathcal{B} \otimes \mathcal{B})-\Im\left(\varphi^{D_{j}(2)}\right) \boldsymbol{R}(\mathcal{B})\right) \boldsymbol{C}_{i}, \tag{48}
\end{equation*}
$$

or equivalently that $\boldsymbol{\phi}^{D_{j}}=\Re\left(\varphi^{D_{j}(1)} \boldsymbol{C}_{i}^{\|}+\varphi^{D_{j}(2)}\left(\boldsymbol{C}_{i}^{\perp}+\mathrm{i} \boldsymbol{C}_{i}^{\odot}\right)\right)$.

### 4.3 New symmetry properties of the mass transport coefficients

Substituting the expansion (6) into the identity $\boldsymbol{V}_{i}=k_{\mathrm{B}} T\left\langle\left\langle\Psi^{D_{i}}, f^{0} \phi\right\rangle\right.$, only the terms in $\phi^{D_{j}}, j \in \mathcal{S}$, and $\phi^{\widehat{\lambda}}$, yield non-null contributions. Expanding $\phi^{D_{j}}, j \in \mathcal{S}$, and $\phi^{\widehat{\lambda}}$, with (45) and (48), using isotropy and denoting by $\boldsymbol{d}_{j}=\left(\boldsymbol{\partial}_{\boldsymbol{x}} p_{j}-\rho_{j} \widetilde{\boldsymbol{b}}_{j}\right) / p$ the unconstrained diffusion driving force for the $j$ th species, we obtain

$$
\begin{align*}
\boldsymbol{V}_{i}=- & \sum_{j \in \mathcal{S}} \\
& \left(D_{i j}^{\|} \boldsymbol{d}_{j}^{\|}+D_{i j}^{\perp} \boldsymbol{d}_{j}^{\perp}+D_{i j}^{\odot} \boldsymbol{d}_{j}^{\odot}\right)  \tag{49}\\
& \quad-\left(\theta_{i}^{\|}\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\|}+\theta_{i}^{\perp}\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\perp}+\theta_{i}^{\odot}\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\odot}\right)
\end{align*}
$$

where we have defined $D_{i j}^{\|}=\left(p k_{\mathrm{B}} T / 3\right)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{D_{j}(1)}, \boldsymbol{\Psi}^{D_{i}}\right\rangle\right\rangle, D_{i j}^{\perp}+\mathrm{i} D_{i j}^{\odot}=\left(p k_{\mathrm{B}} T / 3\right)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{D_{j}(2)}, \boldsymbol{\Psi}^{D_{i}}\right\rangle\right\rangle$, and $\theta_{i}^{\|}=-(1 / 3)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\widehat{\lambda}(1)}, \boldsymbol{\Psi}^{D_{i}}\right\rangle\right\rangle, \theta_{i}^{\perp}+\mathrm{i} \theta_{i}^{\odot}=-(1 / 3)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\widehat{\lambda}(2)}, \boldsymbol{\Psi}^{D_{i}}\right\rangle\right\rangle$. These coefficients are easily rewritten in the symmetrized form

$$
\begin{align*}
D_{i j}^{\|} & =\frac{1}{3} p k_{\mathrm{B}} T \llbracket \varphi^{D_{i}(1)}, \boldsymbol{\varphi}^{D_{j}(1)} \rrbracket  \tag{50}\\
D_{i j}^{\perp}+\mathrm{i} D_{i j}^{\odot} & =\frac{1}{3} p k_{\mathrm{B}} T\left(\llbracket \varphi^{D_{i}(2)}, \varphi^{D_{j}(2)} \rrbracket-\mathrm{i}\left(\left(\varphi^{D_{i}(2)}, \varphi^{D_{j}(2)}\right)\right)\right),  \tag{51}\\
\theta_{i}^{\|} & =-\frac{1}{3} \llbracket \varphi^{D_{i}(1)}, \boldsymbol{\varphi}^{\widehat{\lambda}(1)} \rrbracket  \tag{52}\\
\theta_{i}^{\perp}+\mathrm{i} \theta_{i}^{\odot} & =-\frac{1}{3}\left(\llbracket \varphi^{D_{i}(2)}, \boldsymbol{\varphi}^{\widehat{\lambda}(2)} \rrbracket-\mathrm{i}\left(\left(\boldsymbol{\varphi}^{D_{i}(2)}, \boldsymbol{\varphi}^{\widehat{\lambda}(2)}\right)\right)\right) . \tag{53}
\end{align*}
$$

Note the wrong sign in front of the bracket $((\cdot, \cdot))$ contributions of $D_{i j}^{\perp}+\mathrm{i} D_{i j}^{\odot}$ and $\theta_{i}^{\perp}+\mathrm{i} \theta_{i}^{\odot}$ overlooked in expressions (5.11) and (5.13) of reference [25].

The new symmetry properties of perpendicular and transverse transport coefficients can then be written

$$
\begin{align*}
D_{i j}^{\perp} & =\frac{1}{3} p k_{\mathrm{B}} T \llbracket \varphi^{D_{i}(2)}, \boldsymbol{\varphi}^{D_{j}(2)} \rrbracket=\frac{1}{3} p k_{\mathrm{B}} T \Re \llbracket \varphi^{D_{i}(2)}, \boldsymbol{\varphi}^{D_{j}(2)} \rrbracket,  \tag{54}\\
D_{i j}^{\odot} & =-\frac{1}{3} p k_{\mathrm{B}} T\left(\left(\varphi^{D_{i}(2)}, \varphi^{D_{j}(2)}\right)\right)=-\frac{1}{3} p k_{\mathrm{B}} T \Re\left(\left(\boldsymbol{\varphi}^{D_{i}(2)}, \boldsymbol{\varphi}^{D_{j}(2)}\right)\right),  \tag{55}\\
\theta_{i}^{\perp} & =-\frac{1}{3} \llbracket \varphi^{D_{i}(2)}, \varphi^{\widehat{\lambda}(2)} \rrbracket=-\frac{1}{3} \Re \llbracket \varphi^{D_{i}(2)}, \varphi^{\widehat{\lambda}(2)} \rrbracket,  \tag{56}\\
\theta_{i}^{\odot} & =\frac{1}{3}\left(\left(\varphi^{D_{i}(2)}, \varphi^{\widehat{\lambda}(2)}\right)\right)=\frac{1}{3} \Re\left(\left(\boldsymbol{\varphi}^{D_{i}(2)}, \boldsymbol{\varphi}^{\hat{\lambda}(2)}\right)\right), \tag{57}
\end{align*}
$$

where $\Re$ and $\Im$ denote the real and the imaginary parts. In order to establish (54)(55) for instance, we note that

$$
\begin{equation*}
\Im \llbracket \varphi^{D_{i}(2)}, \boldsymbol{\varphi}^{D_{j}(2)} \rrbracket=\llbracket \Im \varphi^{D_{i}(2)}, \Re \varphi^{D_{j}(2)} \rrbracket-\llbracket \Re \varphi^{D_{i}(2)}, \Im \boldsymbol{\varphi}^{D_{j}(2)} \rrbracket . \tag{58}
\end{equation*}
$$

By using the imaginary part of the second equations in (46), however, we obtain that $\mathcal{F}^{\mathcal{S}}\left(\Im \varphi^{D_{i}(2)}\right)=$ $-B \mathcal{F}^{z, v}\left(\Re \varphi^{D_{i}(2)}\right)$, thanks to $\Im \Psi^{D_{j}}=0$. Since $\mathcal{F}^{\mathcal{S}}$ is self-adjoint we next have

$$
\begin{aligned}
& \llbracket \Im \varphi^{D_{i}(2)}, \Re \varphi^{D_{j}(2)} \rrbracket=\left\langle\left\langle f^{0} \mathcal{F}^{\mathcal{S}} \Im \varphi^{D_{i}(2)}, \Re \varphi^{D_{j}(2)}\right\rangle\right\rangle=-\left\langle\left\langle f^{0} B \mathcal{F}^{z, v} \Re \varphi^{D_{i}(2)}, \Re \varphi^{D_{j}(2)}\right\rangle\right\rangle, \\
& \llbracket \Re \varphi^{D_{i}(2)}, \Im \varphi^{D_{j}(2)} \rrbracket=\left\langle\left\langle f^{0} \Re \varphi^{D_{i}(2)}, \mathcal{F}^{\mathcal{S}} \Im \varphi^{D_{j}(2)}\right\rangle\right\rangle=-\left\langle\left\langle f^{0} \Re \varphi^{D_{i}(2)}, B \mathcal{F}^{z, v} \Re \varphi^{D_{j}(2)}\right\rangle\right\rangle,
\end{aligned}
$$

so that $\llbracket \Im \varphi^{D_{i}(2)}, \Re \varphi^{D_{j}(2)} \rrbracket=\llbracket \Re \varphi^{D_{i}(2)}, \Im \varphi^{D_{j}(2)} \rrbracket=-\left(\left(\Re \varphi^{D_{i}(2)}, \Re \varphi^{D_{j}(2)}\right)\right)$ since the integral operator $\mathcal{F}^{z, v}$ is self-adjoint over the functionals orthogonal to collisional invariants. It is similarly established that $\Im\left(\left(\varphi^{D_{i}(2)}, \varphi^{D_{j}(2)}\right)\right)=0$ so that both quantities $\llbracket \varphi^{D_{i}(2)}, \varphi^{D_{j}(2)} \rrbracket$ and $\left(\left(\varphi^{D_{i}(2)}, \varphi^{D_{j}(2)}\right)\right)$ are real and (51) completes the proof of $(54)(55)$. The relations $(56)(57)$ are established in a similar way. The new symmetry relations (54)-(57) imply in particular that $D_{i j}^{\perp}=D_{j i}^{\perp}, D_{i j}^{\odot}=D_{j i}^{\odot}, \theta_{i}^{\perp}=-\frac{1}{3} \llbracket \varphi^{\widehat{\lambda}(2)}, \varphi^{D_{i}(2)} \rrbracket$, and $\theta_{i}^{\odot}=\frac{1}{3}\left(\left(\varphi^{\widehat{\lambda}(2)}, \varphi^{D_{i}(2)}\right)\right)$. Moreover, proceeding essentially as in [14], one can establish that the nullspace of the real matrices $D^{\|}$and $D^{\perp}$ is spanned by $Y$ in $\mathbb{R}^{n^{s}}$ and that their range is the (euclidean) orthogonal complement of $Y$ in $\mathbb{R}^{n^{s}}$, and similarly that the nullspace of the complex matrix $D^{\perp}+\mathrm{i} D^{\odot}$ is spanned by $Y$ in $\mathbb{C}^{n^{s}}$ and that its range is the (hermitian) orthogonal complement of $Y$ in $\mathbb{C}^{n^{s}}$. In addition, the thermal diffusion ratios satisfy the constraints $\left\langle\theta^{\|}, Y\right\rangle=\left\langle\theta^{\perp}, Y\right\rangle=\left\langle\theta^{\ominus}, Y\right\rangle=0$. Finally, the usual constrained diffusion driving forces $\tilde{\boldsymbol{d}}_{i}=\boldsymbol{d}_{i}-Y_{i} \sum_{j \in \mathcal{S}} \boldsymbol{d}_{j}$ can equivalently be used to formulate the mass fluxes thanks to the properties of transport coefficients.

### 4.4 New symmetry properties of the heat transport coefficients

From the relation $\boldsymbol{q}=-\left\langle\left\langle\Psi^{\widehat{\lambda}}, f^{0} \phi\right\rangle\right\rangle+\sum_{i \in \mathcal{S}}\left(\frac{5}{2} k_{\mathrm{B}} T+\overline{\mathcal{E}_{i}}\right) n_{i} \boldsymbol{V}_{i}$ and the expansion of $\phi$ it is obtained that

$$
\begin{align*}
\boldsymbol{q}= & -\left(\widehat{\lambda}^{\|}\left(\boldsymbol{\partial}_{\boldsymbol{x}} T\right)^{\|}+\widehat{\lambda}^{\perp}\left(\boldsymbol{\partial}_{\boldsymbol{x}} T\right)^{\perp}+\widehat{\lambda}^{\odot}\left(\boldsymbol{\partial}_{\boldsymbol{x}} T\right)^{\odot}\right) \\
& -p \sum_{i \in \mathcal{S}}\left(\theta_{i}^{\|} \boldsymbol{d}_{i}^{\|}+\theta_{i}^{\perp} \boldsymbol{d}_{i}^{\perp}+\theta_{i}^{\odot} \boldsymbol{d}_{i}^{\odot}\right)+\sum_{i \in \mathcal{S}}\left(\frac{5}{2} k_{\mathrm{B}} T+\overline{\mathcal{E}_{i}}\right) n_{i} \boldsymbol{V}_{i}, \tag{59}
\end{align*}
$$

where $\widehat{\lambda}^{\|}=\left(1 / 3 k_{\mathrm{B}} T^{2}\right)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\widehat{\lambda}(1)}, \boldsymbol{\Psi}^{\widehat{\lambda}}\right\rangle\right\rangle$ and $\widehat{\lambda}^{\perp}+\mathrm{i} \widehat{\lambda}^{\odot}=\left(1 / 3 k_{\mathrm{B}} T^{2}\right)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\widehat{\lambda}(2)}, \boldsymbol{\Psi}^{\widehat{\lambda}}\right\rangle\right\rangle$. These coefficients are easily rewritten in the symmetrized form

$$
\begin{align*}
\widehat{\lambda} \| & =\frac{1}{3 k_{\mathrm{B}} T^{2}} \llbracket \varphi^{\widehat{\lambda}(1)}, \varphi^{\widehat{\lambda}(1)} \rrbracket,  \tag{60}\\
\widehat{\lambda}^{\perp}+\mathrm{i} \widehat{\lambda} \odot & =\frac{1}{3 k_{\mathrm{B}} T^{2}}\left(\llbracket \varphi^{\widehat{\lambda}(2)}, \varphi^{\widehat{\lambda}(2)} \rrbracket-\mathrm{i}\left(\left(\varphi^{\widehat{\lambda}(2)}, \varphi^{\widehat{\lambda}(2)}\right)\right)\right) . \tag{61}
\end{align*}
$$

The thermal diffusion coefficients involved in the expansion of $\left\langle\left\langle\boldsymbol{\Psi}^{\widehat{\lambda}}, f^{0} \phi\right\rangle\right\rangle$ are first written in the form $\widehat{\theta}_{i}^{\|}=-(1 / 3)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{D_{i}(1)}, \boldsymbol{\Psi}^{\widehat{\lambda}}\right\rangle\right\rangle$ and $\widehat{\theta}_{i}^{\perp}+\mathrm{i} \widehat{\theta}_{i}^{\odot}=-(1 / 3)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{D_{i}(2)}, \boldsymbol{\Psi}^{\widehat{\lambda}}\right\rangle\right\rangle$, but upon writing these coefficients in a symmetric form $\widehat{\theta}_{i}^{\|}=-\frac{1}{3} \llbracket \boldsymbol{\varphi}^{\widehat{\lambda}(1)}, \varphi^{D_{i}(1)} \rrbracket$, and $\widehat{\theta}_{i}^{\perp}+\mathrm{i} \widehat{\theta}_{i}^{\odot}=-\frac{1}{3}\left(\llbracket \boldsymbol{\varphi}^{\widehat{\lambda}(2)}, \varphi^{D_{i}(2)} \rrbracket-\mathrm{i}\left(\left(\boldsymbol{\varphi}^{\widehat{\lambda}(2)}, \varphi^{D_{i}(2)}\right)\right)\right)$, we obtain from $(52)(53)$ that $\widehat{\theta}_{i}^{\|}=\theta_{i}^{\|}, \quad \widehat{\theta}_{i}^{\perp}=\theta_{i}^{\perp}$, and $\widehat{\theta}_{i}^{\odot}=\theta_{i}^{\odot}, i \in \mathcal{S}$. The new symmetry properties of perpendicular and transverse transport coefficients - established as for diffusion coefficients-then reads

$$
\begin{align*}
& \widehat{\lambda}^{\perp}=\frac{1}{3 k_{\mathrm{B}} T^{2}} \llbracket \varphi^{\widehat{\lambda}(2)}, \varphi^{\widehat{\lambda}(2)} \rrbracket=\frac{1}{3 k_{\mathrm{B}} T^{2}} \Re \llbracket \varphi^{\widehat{\lambda}(2)}, \varphi^{\widehat{\lambda}(2)} \rrbracket,  \tag{62}\\
& \widehat{\lambda}^{\odot}=-\frac{1}{3 k_{\mathrm{B}} T^{2}}\left(\left(\varphi^{\widehat{\lambda}(2)}, \varphi^{\widehat{\lambda}(2)}\right)\right)=-\frac{1}{3 k_{\mathrm{B}} T^{2}} \Re\left(\left(\varphi^{\widehat{\lambda}(2)}, \varphi^{\widehat{\lambda}(2)}\right)\right) . \tag{63}
\end{align*}
$$

As a consequence, the heat-mass transport matrices

$$
A^{\|}=\left(\begin{array}{cc}
\frac{T}{p} \widehat{\lambda}^{\|} & \theta^{\| t} \\
\theta^{\|} & D^{\|}
\end{array}\right), \quad A^{\perp}=\left(\begin{array}{cc}
\frac{T}{p} \widehat{\lambda}^{\perp} & \theta^{\perp t} \\
\theta^{\perp} & D^{\perp}
\end{array}\right), \quad A^{\odot}=\left(\begin{array}{cc}
\frac{T}{p} \widehat{\lambda}^{\odot} & \theta^{\odot t} \\
\theta^{\odot} & D^{\odot}
\end{array}\right)
$$

are real symmetric, $A^{\|}$and $A^{\perp}$ are positive semi-definite, and their nullspace is one dimensional and spanned by $\left(0, Y_{1}, \ldots, Y_{n}\right)^{t}$ where $Y_{k}$ is the mass fraction of the $k$ th species.

### 4.5 Entropy production due to heat and mass transfer

By using the new symmetry properties of transport coefficient, it is now much easier to establish that the entropy production term associated with the heat flux and the diffusion velocities [25]

$$
\begin{equation*}
\Upsilon_{v}=-\left(\boldsymbol{q}-\sum_{i \in \mathcal{S}} \rho_{i} h_{i} \boldsymbol{V}_{i}\right) \cdot \frac{\boldsymbol{\partial}_{\boldsymbol{x}} T}{T^{2}}-\sum_{i \in \mathcal{S}} \frac{p}{T} \boldsymbol{V}_{i} \cdot \boldsymbol{d}_{i} \tag{64}
\end{equation*}
$$

is nonnegative. By using the expressions of $\boldsymbol{V}_{i}$ and $\boldsymbol{q}$, and the new symmetry properties we can indeed write

$$
\begin{aligned}
\Upsilon_{v} \quad & =\frac{1}{T^{2}} \widehat{\lambda} \|\left(\boldsymbol{\partial}_{\boldsymbol{x}} T\right)^{\|} \cdot\left(\boldsymbol{\partial}_{\boldsymbol{x}} T\right)^{\|}+2 \frac{p}{T^{2}} \sum_{i \in \mathcal{S}} \theta_{i}^{\|} \boldsymbol{d}_{i}^{\|} \cdot\left(\boldsymbol{\partial}_{\boldsymbol{x}} T\right)^{\|}+\frac{p}{T} \sum_{i, j \in \mathcal{S}} D_{i j}^{\|} \boldsymbol{d}_{j}^{\|} \cdot \boldsymbol{d}_{i}^{\|} \\
& +\frac{1}{T^{2}} \widehat{\lambda}^{\perp}\left(\boldsymbol{\partial}_{\boldsymbol{x}} T\right)^{\perp} \cdot\left(\boldsymbol{\partial}_{\boldsymbol{x}} T\right)^{\perp}+2 \frac{p}{T^{2}} \sum_{i \in \mathcal{S}} \theta_{i}^{\perp} \boldsymbol{d}_{i}^{\perp} \cdot\left(\boldsymbol{\partial}_{\boldsymbol{x}} T\right)^{\perp}+\frac{p}{T} \sum_{i, j \in \mathcal{S}} D_{i j}^{\perp} \boldsymbol{d}_{j}^{\perp} \cdot \boldsymbol{d}_{i}^{\perp}
\end{aligned}
$$

so that

$$
\Upsilon_{v}=\frac{p}{T}\left(\left\langle A^{\|} x^{\|}, x^{\|}\right\rangle+\left\langle A^{\perp} x^{\perp}, x^{\perp}\right\rangle\right)
$$

with $x_{0}^{\|}=\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\|}, x_{i}^{\|}=\left(\boldsymbol{d}_{i}\right)^{\|}, x_{0}^{\perp}=\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\perp}$, and $x_{i}^{\perp}=\left(\boldsymbol{d}_{i}\right)^{\perp}$. Note in particular that the terms $\sum_{i \in \mathcal{S}} \widehat{\theta}_{i}^{\odot} \boldsymbol{d}_{i}^{\odot} \cdot\left(\boldsymbol{\partial}_{\boldsymbol{x}} T\right)^{\perp}+\sum_{i \in \mathcal{S}} \theta_{i}^{\odot}\left(\boldsymbol{\partial}_{\boldsymbol{x}} T\right)^{\odot} \cdot \boldsymbol{d}_{i}^{\perp}$ and $\sum_{i, j \in \mathcal{S}} D_{i j}^{\odot} \boldsymbol{d}_{i}^{\perp} \cdot \boldsymbol{d}_{j}^{\odot}$ appearing in the expression of $\Upsilon_{v}$ in reference [25] all vanish since $\widehat{\theta}=\theta, D^{\odot}$ is symmetric, and $\mathbf{x}^{\odot} \cdot \mathbf{y}^{\perp}+\mathbf{x}^{\perp} \cdot \mathbf{y}^{\odot}=0$ for any vectors $\mathbf{x}$ and $\mathbf{y}$. The term $\sum_{i, j \in \mathcal{S}} D_{i j}^{\odot} \boldsymbol{d}_{i}^{\perp} \cdot \boldsymbol{d}_{j}^{\odot}$ was erroneously typed $\sum_{i, j \in \mathcal{S}} D_{i j}^{\odot} \boldsymbol{d}_{i}^{\perp} \cdot \boldsymbol{d}_{j}^{\perp}$ in reference [25].

### 4.6 First order transport linear systems associated with $D$

The vector integral equations associated with multicomponent diffusion coefficients are in the form $\left(\mathcal{F}^{\mathcal{S}}+\delta_{2 \mid} B \mathcal{F}^{z, v}\right)\left(\varphi^{D_{j}(\mathrm{I})}\right)=\Psi^{D_{j}}$, with $\mathrm{I} \in\{1,2\}, j \in \mathcal{S}$, and

$$
\boldsymbol{\Psi}^{D_{j}}=\sum_{k \in \mathcal{S}} \sqrt{2 / m_{k} k_{\mathrm{B}} T}\left(\delta_{j k}-Y_{k}\right) / n_{k} \phi^{1000 k}
$$

where $\phi^{1000 k}=\left(\boldsymbol{w}_{k} \delta_{k i}\right)_{i \in \mathcal{S}}[14]$. By isotropy, the variational approximation space $\mathcal{A}_{[00]}^{D}$ to be considered in the first place is the space spanned by $\phi^{1000 k}, k \in \mathcal{S}$, and we will denote by $\varphi_{[00]}^{D_{j}(1)}$ the corresponding approximation.

For convenience, $\varphi_{[00]}^{D_{j}(1)}$ is taken in the form

$$
\varphi_{[00]}^{D_{j}(I)}=\frac{\sqrt{2}}{p \sqrt{k_{\mathrm{B}} T}} \sum_{k \in \mathcal{S}} \sqrt{m_{k}} \alpha_{[00] k}^{00 D_{j}(1)} \phi^{1000 k}, \quad \mathrm{I} \in\{1,2\}, \quad j \in \mathcal{S} .
$$

The matrix associated with the variational procedure is denoted by $\Delta_{[00]}$ and is rescaled such that $\Delta_{[00] k l}=\left(2 \sqrt{m_{k} m_{l}} / 3 p\right) \llbracket \phi^{1000 k}, \phi^{1000 l} \rrbracket, k, l \in \mathcal{S}$. We also rescale the right member $\beta_{[00] k}^{00 D_{j}}$ by defining $\beta_{[00] k}^{00 D_{j}}=\left(\sqrt{2 m_{k} k_{\mathrm{B}} T} / 3\right)\left\langle\left\langle f^{0} \phi^{1000 k}, \Psi^{D_{j}}\right\rangle\right\rangle, k \in \mathcal{S}$. We then have $\Delta_{[00]}, \Delta_{[00]}^{B} \in \mathbb{R}^{n^{s}, n^{s}}, \beta_{[00]}^{D_{j}}, \alpha_{[00]}^{D_{j}(1)} \in \mathbb{R}^{n^{s}}$, $\alpha_{[00]}^{D_{j}(2)} \in \mathbb{C}^{n^{s}}$, and the linear systems for $\alpha_{[00]}^{D_{j}(1)}=\left(\alpha_{[00] k}^{00 D_{j}(1)}\right)_{k \in \mathcal{S}}$ and $\alpha_{[00]}^{D_{j}(2)}=\left(\alpha_{[00] k}^{00 D_{j}(2)}\right)_{k \in \mathcal{S}}$ are in the form

$$
\left\{\begin{array} { r l } 
{ \Delta _ { [ 0 0 ] } \alpha _ { [ 0 0 ] } ^ { D _ { j } ( 1 ) } } & { = \beta _ { [ 0 0 ] } ^ { D _ { j } } , }  \tag{65}\\
{ \langle \alpha _ { [ 0 0 ] } ^ { D _ { j } ( 1 ) } , Y \rangle } & { = 0 , }
\end{array} \quad \left\{\begin{array}{rl}
\left(\Delta_{[00]}+\mathrm{i} \Delta_{[00]}^{B}\right) \alpha_{[00]}^{D_{j}(2)} & =\beta_{[00]}^{D_{j}}, \\
\left\langle\alpha_{[00]}^{D_{j}(2)}, Y\right\rangle & =0 .
\end{array}\right.\right.
$$

The coefficients of the matrix $\Delta_{[00]}$ are given by

$$
\Delta_{[00] k k}=\sum_{\substack{l \in \mathcal{S} \\ l \neq k}} \frac{X_{k} X_{l}}{\mathcal{D}_{k l}}, \quad k \in \mathcal{S}, \quad \Delta_{[00] k l}=-\frac{X_{k} X_{l}}{\mathcal{D}_{k l}}, \quad k, l \in \mathcal{S}, \quad k \neq l,
$$

where $\mathcal{D}_{k l}$ is the binary diffusion coefficient of the species pair $(k, l)$, and the right members $\beta_{[00]}^{D_{j}}=$ $\left(\beta_{[00] k}^{00 D_{j}}\right)_{k \in \mathcal{S}}$ are given by

$$
\beta_{[00] k}^{00 D_{j}}=\delta_{j k}-Y_{k}, \quad k, j \in \mathcal{S} .
$$

The constraint vector is $Y=\left(Y_{1}, \ldots, Y_{n^{s}}\right)^{t}$ where $Y_{k}$ is the mass fraction of the $k$ th species and we have denoted by $\langle x, y\rangle=\sum_{k \in \mathcal{S}} x_{k} \bar{y}_{k}$ the Hermitian scalar product. The binary diffusion coefficient $\mathcal{D}_{k l}$ can also be written $\mathcal{D}_{k l}=3 k_{\mathrm{B}} T / 16 n m_{k l} \Omega_{k l}^{(1,1)}$ where $m_{k l}=m_{k} m_{l} /\left(m_{k}+m_{l}\right)$ is the reduced mass of the species pair $(k, l)$. Moreover, we have

$$
\Delta_{[00]}^{B}=(\mathbb{I}-Y \otimes U) \mathcal{D}^{B}(\mathbb{I}-U \otimes Y),
$$

where $\mathcal{D}^{B}$ is the diagonal matrix $\mathcal{D}_{k l}^{B}=\delta_{k l} n_{k} e_{k} B / p$ and $U=(1, \ldots, 1)^{t} \in \mathbb{R}^{n^{s}}$.
The real matrix $\Delta_{[00]}$ is symmetric positive definite, $N\left(\Delta_{[00]}\right)=\mathbb{R} U, R\left(\Delta_{[00]}\right)=U^{\perp}$ in $\mathbb{R}^{n^{s}}$ [14], whereas the complex matrix $\Delta_{[00]}+\mathrm{i} \Delta_{[00]}^{B}$ is such that $N\left(\Delta_{[00]}+\mathrm{i} \Delta_{[00]}^{B}\right)=\mathbb{C} U, R\left(\Delta_{[00]}+\mathrm{i} \Delta_{[00]}^{B}\right)=U^{\perp}$ in $\mathbb{C}^{n^{s}}$, where the nullspace and range of a matrix $A$ are denoted by $N(A)$ and $R(A)$, respectively. The resulting approximated diffusion coefficients are denoted by $D_{[00]}^{\|}, D_{[00]}^{\perp}, D_{[00]}^{\odot}$, and are given by

$$
\begin{align*}
D_{[00] i j}^{\|} & =\left\langle\alpha_{[00]}^{D_{j}(1)}, \beta_{[00]}^{D_{i}}\right\rangle=\alpha_{[00] i}^{00 D_{j}(1)}=\alpha_{[00] j}^{00 D_{i}(1)},  \tag{66}\\
D_{[00] i j}^{\perp}+\mathrm{i} D_{[00] i j}^{\odot} & =\left\langle\alpha_{[00]}^{D_{j}(2)}, \beta_{[00]}^{D_{i}}\right\rangle=\alpha_{[00] i}^{00 D_{j}(2)}=\alpha_{[00] j}^{00 D_{i}(2)} \tag{67}
\end{align*}
$$

In addition, for all $a>0$ we have $D_{[00]}^{\|}=\left(\Delta_{[00]}+a Y \otimes Y\right)^{-1}-(1 / a) U \otimes U$ and also $D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}=$ $\left(\Delta_{[00]}+\mathrm{i} \Delta_{[00]}^{B}+a Y \otimes Y\right)^{-1}-(1 / a) U \otimes U$.

Projected standard iterative techniques as well as projected generalized conjugate gradient methods can be used to solve the constrained singular systems associated with the first order diffusion coefficients (65). Iterative techniques for the real transport linear system associated with the real matrix $D_{[00]}^{\|}$are similar to that of non-ionized mixtures which have been investigated comprehensively [23, 14]. We thus only discuss in the following the evaluation by iterative techniques of the complex matrix $D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}$, by solving $\left(\Delta_{[00]}+\mathrm{i} \Delta_{[00]}^{B}\right)\left(D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}\right)=\mathbb{I}-Y \otimes U$ with the constraint $\left(D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}\right) Y=0$. In this situation, it is generally more efficient to solve iteratively the linear systems in their complex form rather than in their equivalent real form [22].

When only the diffusion velocities are required-and not the diffusion coefficients-a complex form of the Stefan-Maxwell equations can be solved by using orthogonal errors algorithms [20, 27]. In the absence of Soret effect, these generalized complex Stefan-Maxwell equations are in the form

$$
\begin{equation*}
\left(\Delta_{[00]}+\mathrm{i} \Delta_{[00]}^{B}\right)\left(\boldsymbol{V}^{\perp}-\mathrm{i} \boldsymbol{V}^{\odot}\right)=\boldsymbol{d}^{\perp}-\mathrm{i} \boldsymbol{d}^{\odot}-Y \sum_{l \in \mathcal{S}}\left(\boldsymbol{d}_{l}^{\perp}-\mathrm{i} \boldsymbol{d}_{l}^{\odot}\right), \tag{68}
\end{equation*}
$$

where $\boldsymbol{V}^{\diamond}=\left(\boldsymbol{V}_{1}^{\diamond}, \ldots, \boldsymbol{V}_{n^{s}}^{\diamond}\right)^{t}, \boldsymbol{d}^{\diamond}=\left(\boldsymbol{d}_{1}^{\diamond}, \ldots, \boldsymbol{d}_{n^{s}}^{\diamond}\right)^{t}, \diamond \in\{\|, \perp, \odot\}$ and $Y=\left(Y_{1}, \ldots, Y_{n^{s}}\right)^{t}$. The proper modification of the complex Stefan-Maxwell equations in the presence of Soret effect are discussed in Section 5. The vectors $\boldsymbol{d}^{\diamond}=\left(\boldsymbol{d}_{i}^{\diamond}\right)_{i \in \mathcal{S}}, \diamond \in\{\|, \perp, \odot\}$, are the unconstrained diffusion driving forces and $\widetilde{\boldsymbol{d}}_{i}^{\diamond}=\boldsymbol{d}_{i}^{\diamond}-Y_{i} \sum_{j \in \mathcal{S}} \boldsymbol{d}_{j}^{\diamond}, \tilde{\boldsymbol{d}}^{\diamond}=\left(\tilde{\boldsymbol{d}}_{i}^{\diamond}\right)_{i \in \mathcal{S}}, \diamond \in\{\|, \perp, \odot\}$, are the corresponding constrained diffusion driving forces which sum up to zero. Only the diffusion velocities are required when an explicit time marching technique is use to compute a multicomponent flow for instance. More generally, when fractional steps are used, the diffusion velocities are also sufficient-that is, the diffusion coefficient matrices are not needed-if the 'diffusion time step' is taken to be explicit.

On the other hand, when the diffusion coefficients are to be evaluated, as is typically the case if an implicit time marching method is used, it is first possible to use a direct inversion method by forming $D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}=\left(\Delta_{[00]}+\mathrm{i} \Delta_{[00]}^{B}+a Y \otimes Y\right)^{-1}-(1 / a) U \otimes U$ where $a>0$. The $\left(n^{s}\right)^{2}$ coefficients are then evaluated within $\mathcal{O}\left(\left(n^{s}\right)^{3}\right)$ operations. It is nevertheless possible to evaluate approximate coefficients within $\mathcal{O}\left(\left(n^{s}\right)^{2}\right)$ operations by using standard iterative techniques. These techniques maintain a linear
relation between the right members and the diffusion coefficients so that the resulting algorithms can directly be rewritten in terms of diffusion matrices. More specifically, in order to solve iteratively $\left(\Delta_{[00]}+\mathrm{i} \Delta_{[00]}^{B}\right)\left(D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}\right)=\mathbb{I}-Y \otimes U$ with the constraint $\left(D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}\right) Y=0$, we introduce the splitting $\Delta_{[00]}+\mathrm{i} \Delta_{[00]}^{B}=M-Z$ where $M=\mathcal{D}+\mathrm{i} \Delta_{[00]}^{B}$ and $\mathcal{D}$ is a diagonal matrix such that $\mathcal{D}_{k k}=\Delta_{[00] k k} /\left(1-Y_{k}\right)$. Denoting by $T$ the iteration matrix $T=M^{-1} Z$, we then have the convergent asymptotic expansion

$$
D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}=\sum_{\mathrm{j}=0}^{\infty}(P T)^{\mathrm{j}} P M^{-1} P^{t}
$$

where $P=\mathbb{I}-U \otimes Y$ denotes the projector matrix onto $Y^{\perp}$ parallel to $U$. This expansion can be shown to be convergent with a spectral radius of the product $P T=P M^{-1} Z$ strictly lower than unity, and this spectral radius is always lower in the magnetized case than in the unmagnetized case where the matrix $\Delta_{[00]}^{B}$ vanishes [27]. Furthermore, since $\Delta_{[00]}^{B}=(\mathbb{I}-Y \otimes U) \mathcal{D}^{B}(\mathbb{I}-U \otimes Y)$, the inverse of $M=\mathcal{D}+\mathrm{i} \Delta_{[00]}^{B}$ can easily be expressed in terms of the inverse of the diagonal matrix $\mathcal{D}+\mathrm{i}^{B}$ in such a way that the iterates are easily evaluated [27]. Various approximations can then be obtained by truncating this convergent series. The first approximation $\left(D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}\right)^{[1]}$ generalizes the Hirschfelder-Curtiss approximation with a mass corrector $[36,23,24]$ to the magnetized case

$$
\begin{equation*}
\left.\left(D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}\right)\right)^{[1]}=\mathcal{M}+\frac{\mathcal{M} \mathcal{D} U \otimes \mathcal{M D D} U}{\langle\mathcal{D} U-\mathcal{D \mathcal { M D } U , U \rangle},} \tag{69}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathcal{M}=\left(\mathcal{D}+\mathrm{i} \mathcal{D}^{B}\right)^{-1}-\frac{\left(\mathcal{D}+\mathrm{i} \mathcal{D}^{B}\right)^{-1} Y \otimes\left(\mathcal{D}+\mathrm{i} \mathcal{D}^{B}\right)^{-1} Y}{\left\langle\left(\mathcal{D}+\mathrm{i} \mathcal{D}^{B}\right)^{-1} Y, Y\right\rangle} . \tag{70}
\end{equation*}
$$

The second order approximation can further be written

$$
\begin{equation*}
\left(D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}\right)^{[2]}=\left(D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}\right)^{[1]}+\left(D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}\right)^{[1]}\left(\mathcal{D}-\Delta_{[00]}\right)\left(D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}\right)^{[1]}, \tag{71}
\end{equation*}
$$

and yields a more accurate approximation. Since $\mathcal{M}$ is a rank one perturbation of the diagonal matrix $\left(\mathcal{D}+\mathrm{iD} \mathcal{D}^{B}\right)^{-1}$, the first iterate is also a rank two perturbation of the matrix $\left(\mathcal{D}+\mathrm{i} \mathcal{D}^{B}\right)^{-1}$ so that both iterates $\left(D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}\right)^{[1]}$ and $\left(D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}\right)^{[2]}$ are evaluated within $O\left(\left(n^{s}\right)^{2}\right)$ operations. The interest of these algorithms is that they perform well whatever the intensity of the magnetic field since the complete matrix $\mathrm{i} \Delta_{[00]}^{B}$ has been taken into account in the splitting matrix $M=\mathcal{D}+\mathrm{i} \Delta_{[00]}^{B}$. They do not perform well, however, independently of the ionization degree and convergence rates deteriorate as ionization levels increase as investigated by Garcia Muñoz [35] in the unmagnetized case.

The numerical tests conducted with weakly ionized air at temperature 10000 K have shown that the second iterate is generally within one percent of the exact corresponding first order matrix $D_{[00]}^{\perp}+\mathrm{i} D_{[00]}^{\odot}$ for usual matrix norms provided the ionization level is below $10^{-2}$. When the ionization level increases, it becomes more and more difficult to evaluate the diffusion coefficients matrices by using standard iterative techniques and in this situation, we recommend a direct inversion method.
Remark : Taking into account the electron/heavy particles coefficients in the splitting matrix $M=$ $\mathcal{D}^{\prime}+\mathrm{i} \Delta_{[00]}^{B}$ with $\mathcal{D}_{k l}^{\prime}=\mathcal{D}_{k l}$, if $k \neq n^{s}$ and $l \neq n^{s}$, and $\mathcal{D}_{k l}^{\prime}=\Delta_{[00] k l}$ otherwise, assuming that the electron is the last species $k=n^{s}$, only slightly improves the convergence rates. Similarly, defining $\widehat{D}_{[00]}=D_{[00]}-D_{[00]} z \otimes D_{[00]} z /\left\langle z, D_{[00]} z\right\rangle, \widehat{\Delta}_{[00]}=\Delta_{[00]}-z^{*} \otimes z^{*} /\left\langle D_{[00]} z, z\right\rangle$, where $z^{*}=z-\langle z, U\rangle Y$, one can establish that $\widehat{D}_{[00]}$ is the generalized inverse of $\widehat{\Delta}_{[00]}$ with prescribed nullspace $\mathbb{R} Y \oplus \mathbb{R} z$ and range $\operatorname{span}\left(Y, z^{*}\right)^{\perp}$. In the asymptotic limit of vanishing electron mass, the matrix $\widehat{D}_{[00]}$ has a finite limit at variance with $D_{[00]}$ of which the coefficient $D_{[00] n^{s} n^{s}}$ is exploding [26]. It is then possible to define an iterative technique by first evaluating $D_{[00]} z$ and then $\widehat{D}_{[00]}$ instead of $D_{[00]}$, but, once again, it only slightly improves the convergence rates.

### 4.7 Higher order linear systems associated with $D$ and electrical conductivities

Higher order approximations of the diffusion matrices, also accounting for the energy of the molecules, require to consider larger linear systems of size $2 n^{s}+n^{p}$ where $n^{p}$ denotes the number of polyatomic
species of the mixture, that is, the number of species with at least two different internal energy states. The corresponding systems can be written in the form

$$
\left\{\begin{array} { r l } 
{ L \alpha ^ { D _ { j } ( 1 ) } } & { = \beta ^ { D _ { j } } , }  \tag{72}\\
{ \langle \alpha ^ { D _ { j } ( 1 ) } , \mathcal { Y } \rangle } & { = 0 , }
\end{array} \quad \left\{\begin{array}{rl}
\left(L+\mathrm{i} L^{B}\right) \alpha^{D_{j}(2)} & =\beta^{D_{j}} \\
\left\langle\alpha^{D_{j}(2)}, \mathcal{Y}\right\rangle & =0,
\end{array}\right.\right.
$$

where the matrices $L, L^{B} \in \mathbb{R}^{2 n^{s}+n^{p}, 2 n^{s}+n^{p}}$ are detailed in the next section and the vectors $\beta^{D_{j}}, \mathcal{Y} \in$ $\mathbb{R}^{2 n^{s}+n^{p}}$ are given by $\beta^{D_{j}}=\left(\beta_{[00]}^{D_{j}},(0)_{k \in \mathcal{S}},(0)_{k \in \mathcal{P}}\right)^{t}, j \in \mathcal{S}$, and by $\mathcal{Y}=\left(Y,(0)_{k \in \mathcal{S}},(0)_{k \in \mathcal{P}}\right)^{t}$. The higher order coefficients are given by

$$
\begin{align*}
D_{i j}^{\|} & =\left\langle\alpha^{D_{j}(1)}, \beta^{D_{i}}\right\rangle=\alpha_{i}^{00 D_{j}(1)}=\alpha_{j}^{00 D_{i}(1)}  \tag{73}\\
D_{i j}^{\perp}+\mathrm{i} D_{i j}^{\odot} & =\left\langle\alpha^{D_{j}(2)}, \beta^{D_{i}}\right\rangle=\alpha_{i}^{00 D_{j}(2)}=\alpha_{j}^{00 D_{i}(2)} \tag{74}
\end{align*}
$$

Defining $\mathcal{V}^{\|}=\sum_{j \in \mathcal{S}} \alpha^{D_{j}(1)} \boldsymbol{d}_{j}^{\|}$and $\mathcal{V}^{\perp}-\mathrm{i} \mathcal{V}^{\odot}=\sum_{j \in \mathcal{S}} \alpha^{D_{j}(2)}\left(\boldsymbol{d}_{j}^{\perp}-\mathrm{i} \boldsymbol{d}_{j}^{\odot}\right)$ the associated complex generalized Stefan-Maxwell equations are in the form

$$
\begin{equation*}
\left(L+\mathrm{i} L^{B}\right)\left(\mathcal{V}^{\perp}-\mathrm{i} \mathcal{V}^{\odot}\right)=\sum_{j \in \mathcal{S}} \beta^{D_{j}}\left(\boldsymbol{d}_{j}^{\perp}-\mathrm{i} \boldsymbol{d}_{j}^{\odot}\right) \tag{75}
\end{equation*}
$$

where $\mathcal{V}^{\diamond}=\left(\mathcal{V}_{1}^{\diamond}, \ldots, \mathcal{V}_{n^{s}}^{\diamond}\right)^{t}$, and $\mathcal{V}_{k}^{00 \diamond}=\boldsymbol{V}_{k}^{\diamond}, \diamond \in\{\|, \perp, \odot\}$. The corresponding modifications required in order to take into account thermal diffusion are discussed in Section 5.

The same general strategy can be used to evaluate higher order diffusion mass fluxes as for first order fluxes investigated in the preceding section. When only the diffusion velocities are required, an orthogonal error method can be used to solve the generalized Stefan-Maxwell equations. When the diffusion matrices are also required, either standard iterative algorithms or direct methods can be used to solve the corresponding transport linear systems. The same standard iterative algorithms can be used for instance by using splittings in the form $L+\mathrm{i} L^{B}=\mathcal{M}-\mathcal{Z}$ with $\mathcal{M}=\mathcal{D}+\mathrm{i} L^{B}$ where $\mathcal{D}$ is a diagonal matrix or a block diagonal matrix as described in [14]. Denoting by $\mathcal{T}$ the iteration matrix $\mathcal{T}=\mathcal{M}^{-1} \mathcal{Z}$, we then have the convergent asymptotic expansion

$$
D^{\perp}+\mathrm{i} D^{\odot}=\Pi\left(\sum_{\mathrm{j}=0}^{\infty}(\mathcal{P J})^{\left.\mathrm{j} \mathcal{P} \mathcal{M}^{-1} \mathcal{P}^{t}\right) \Pi^{t}, ~, ~}\right.
$$

where $\mathcal{M}=\mathbb{I}-\mathcal{U} \otimes \mathcal{Y}$ denotes the projector matrix onto $\mathcal{Y}^{\perp}$ parallel to $\mathcal{U}$ where $\mathcal{U}$ is defined by $\mathcal{U}=\left(U,(0)_{k \in \mathcal{S}},(0)_{k \in \mathcal{P}}\right)^{t}$ and $\Pi \in \mathbb{R}^{n^{s}, 2 n^{s}+n^{p}}$ is the rectangular matrix $\Pi=[\mathbb{I}, 0,0]$. This expansion can be shown to be convergent with a spectral radius of the product $\mathcal{P T}=\mathcal{P} \mathcal{M}^{-1} \mathcal{Z}$ strictly lower than unity. The second order iterate $\left(D^{\perp}+\mathrm{i} D^{\odot}\right)^{[2]}$ is a good trade off between precision and computional costs.

The higher order effects usually have a minor impact on the diffusion matrix of neutral species mixtures [14]. They have a more important impact, however, on ionized mixtures. Our numerical test for high temperature air have shown that the relative error in matrix norms $\left\|D^{\|}-D_{[00]}^{\|}\right\| /\left\|D^{\|}\right\|$, $\left\|D^{\perp}-D_{[00]}^{\perp}\right\| /\left\|D^{\perp}\right\|$, and $\left\|D^{\odot}-D_{[00]}^{\odot}\right\| /\left\|D^{\|}\right\|$, can be large for ionization rates above $10^{-2}$ and remain below $10^{-2}$ only when the ionization rate is below $10^{-3}$. The same is true for $\left\|D^{\odot}-D_{[00]}^{\odot}\right\| /\left\|D^{\odot}\right\|$, unless $B$ is small but then both $D^{\odot}$ and $D_{[00]}^{\odot}$ are small. Above the ionization level $10^{-3}$, it is recommended to use the higher order approximations diffusion matrices $D$ and to use direct methods.

Higher order effects due to the energy of the molecules are always important, however, even for weakly ionized mixtures, in order to evaluate the electrical conductivities [21, 3, 6, 7]. The electrical conductivities $\sigma^{\|}, \sigma^{\perp}$, and $\sigma^{\odot}$, are defined by

$$
p \sigma^{\|}=\sum_{i, j \in \mathcal{S}} D_{i j}^{\|} n_{i} e_{i} n_{j} e_{j}, \quad p \sigma^{\perp}=\sum_{i, j \in \mathcal{S}} D_{i j}^{\perp} n_{i} e_{i} n_{j} e_{j}, \quad p \sigma^{\odot}=\sum_{i, j \in \mathcal{S}} D_{i j}^{\odot} n_{i} e_{i} n_{j} e_{j}
$$

and since the species charge $e_{i}, i \in \mathcal{S}$, can be of different sign, cancellation of significating digits may arise so that using only the first order diffusion coefficients may lead to large errors in the conductivities, as shown in particular by Bruno and coworkers in the monatomic approximation [3, 6, 7]. In the numerical simulations by Bruno and coworkers, the errors are even amplified because of the Ramsauer minimum in the Argon-electron collision cross sections [6, 7].

In order to improve the accuracy of the electrical conductivities, a first possibility is to compute the higher order diffusion coefficients $D$ and then the corresponding electrical conductivities. A second
possibility, however, is to use the first order diffusion coefficients $D_{[00]}$ in the species equations-when they are sufficiently accurate - and to only evaluate the solutions $\zeta^{(1)}$ and $\zeta^{(2)}$ of the linear systems

$$
\left\{\begin{array} { r l } 
{ L \zeta ^ { ( 1 ) } } & { = \sum _ { j \in \mathcal { S } } n _ { j } e _ { j } \beta ^ { D _ { j } } , }  \tag{76}\\
{ \langle \zeta ^ { ( 1 ) } , \mathcal { Y } \rangle } & { = 0 , }
\end{array} \left\{\begin{array}{rl}
\left(L+\mathrm{i} L^{B}\right) \zeta^{(2)} & =\sum_{j \in \mathcal{S}} n_{j} e_{j} \beta^{D_{j}} \\
\left\langle\zeta^{(2)}, \mathcal{Y}\right\rangle & =0
\end{array}\right.\right.
$$

Once the vectors $\zeta^{(1)}$ and $\zeta^{(2)}$ are evaluated, the electrical conductivities are then be obtained from

$$
p \sigma^{\|}=\sum_{j \in \mathcal{S}} n_{j} e_{j} \zeta_{j}^{(1)}, \quad p\left(\sigma^{\perp}+\mathrm{i} \sigma^{\odot}\right)=\sum_{j \in \mathcal{S}} n_{j} e_{j} \zeta_{j}^{(2)}
$$

The systems (76) can be solved by using a generalized conjugate gradient procedure like an othogonal error algorithm which converge within a few iterations independently of the magnetic field.

### 4.8 Transport linear systems associated with $\hat{\lambda}$ and $\theta$

The vector integral equations associated with the partial thermal conductivity are in the form $\left(\mathcal{F}^{\mathcal{S}}+\right.$ $\left.\delta_{2 \mid} B \mathcal{F}^{z}, v\right)\left(\boldsymbol{\varphi}^{\widehat{\lambda}(\mathrm{I})}\right)=\boldsymbol{\Psi}^{\widehat{\lambda}}$, with $\mathrm{I}=1,2$, and

$$
\Psi^{\widehat{\lambda}}=\sum_{k \in \mathcal{S}} \sqrt{2\left(k_{\mathrm{B}} T\right)^{3} / m_{k}} \phi^{1010 k}+\sum_{k \in \mathcal{P}} \sqrt{2\left(k_{\mathrm{B}} T\right)^{3} / m_{k}} \phi^{1001 k}
$$

where $\phi^{1010 k}=\left(\left(\frac{5}{2}-\boldsymbol{w}_{k} \cdot \boldsymbol{w}_{k}\right) \boldsymbol{w}_{k} \delta_{k i}\right)_{i \in \mathcal{S}}, k \in \mathcal{S}, \phi^{1001 k}=\left(\left(\bar{\epsilon}_{k}-\epsilon_{k K}\right) \boldsymbol{w}_{k} \delta_{k i}\right)_{i \in \mathcal{S}}, k \in \mathcal{P}, \mathcal{P}$ denotes the set of polyatomic species, and $n^{p}$ the number of polyatomic species [14]. The variational approximation space $\mathcal{A}^{\widehat{\lambda}}$ to be considered in the first place is the space spanned by $\phi^{1000 k}, k \in \mathcal{S}, \phi^{1010 k}, k \in \mathcal{S}$, and $\phi^{1001 k}, k \in \mathcal{P}$, and we will denote by $\varphi^{\widehat{\lambda}(l)}$ the corresponding approximation.

For convenience, $\varphi^{\widehat{\lambda}(\mathrm{I})}$ is taken in the form

$$
\varphi^{\widehat{\lambda}(\mathrm{I})}=\sqrt{2 k_{\mathrm{B}} T}\left(\sum_{k \in \mathcal{S}} \sqrt{m_{k}}\left(\alpha_{k}^{00 \widehat{\lambda}(\mathrm{I})} \phi^{1000 k}+\alpha_{k}^{10 \widehat{\lambda}(\mathrm{I})} \phi^{1010 k}\right)+\sum_{k \in \mathcal{P}} \sqrt{m_{k}} \alpha_{k}^{01 \widehat{\lambda}(\mathrm{I})} \phi^{1001 k}\right), \quad \mathrm{I}=1,2 .
$$

The matrix associated with the variational procedure is denoted by $L$ and is rescaled such that $L_{k l}=$ $\left(2 \sqrt{m_{k} m_{l}} / 3 p\right) \llbracket \phi^{10 r k}, \phi^{10 s l} \rrbracket,(r, k),(s, l) \in\{00\} \times \mathcal{S} \cup\{10\} \times \mathcal{S} \cup\{01\} \times \mathcal{P}$. We also rescale the right member $\beta_{k}^{r \widehat{\lambda}}=\sqrt{2 m_{k} / k_{\mathrm{B}} T} / 3 p\left\langle\left\langle f^{0} \phi^{1000 k}, \widehat{\lambda}\right\rangle,(r, k) \in\{00\} \times \mathcal{S} \cup\{10\} \times \mathcal{S} \cup\{01\} \times \mathcal{P}\right.$. We then have $L \in \mathbb{R}^{2 n^{s}+n^{p}, 2 n^{s}+n^{p}}, \beta^{\widehat{\lambda}} \in \mathbb{R}^{2 n^{s}+n^{p}}$, and the linear system for $\alpha^{\widehat{\lambda}(1)} \in \mathbb{R}^{2 n^{s}+n^{p}}$ and $\alpha^{\widehat{\lambda}(2)} \in \mathbb{C}^{2 n^{s}+n^{p}}$ are in the form

$$
\left\{\begin{array} { r l } 
{ L \alpha ^ { \widehat { \lambda } ( 1 ) } } & { = \beta ^ { \widehat { \lambda } } , } \\
{ \langle \alpha ^ { \widehat { \lambda } ( 1 ) } , \mathcal { Y } \rangle } & { = 0 , }
\end{array} \quad \left\{\begin{array}{rl}
\left(L+\mathrm{i} L^{B}\right) \alpha^{\widehat{\lambda}(2)} & =\beta^{\widehat{\lambda}}, \\
\left\langle\alpha^{\widehat{\lambda}(2)}, \mathcal{Y}\right\rangle & =0 .
\end{array}\right.\right.
$$

The coefficients of the matrix $L$ are given in reference [14] and are summarized in Section 5.3, the constraint vector $\mathcal{Y} \in \mathbb{R}^{2 n^{s}+n^{p}}$ is given by $\mathcal{Y}=\left(Y,(0)_{k \in \mathcal{S}},(0)_{k \in \mathcal{P}}\right)^{t}$, and the right member $\beta^{\widehat{\lambda}}$ is such that $\beta_{k}^{r \widehat{\lambda}}=0,(r, k) \in\{00\} \times \mathcal{S}, \beta_{k}^{r \widehat{\lambda}}=\frac{5}{2} X_{k},(r, k) \in\{10\} \times \mathcal{S}$, and $\beta_{k}^{r \widehat{\lambda}}=\mathfrak{c}_{k}^{\text {int }} X_{k} / k_{\mathrm{B}},(r, k) \in\{01\} \times \mathcal{P}$, where $\mathfrak{c}_{k}^{\mathrm{int}}$ is the internal heat capacity of the $k$ th species per molecule. On the other hand, the matrix $L^{B}$ is in the form

$$
L^{B}=(\mathbb{I}-\mathcal{Y} \otimes \mathcal{U}) \mathrm{L}^{B}(\mathbb{I}-\mathcal{U} \otimes \mathcal{Y})
$$

where $\mathrm{L}^{B}$ is the diagonal matrix $\left(\mathrm{L}^{B}\right)_{k l}^{r s}=\delta_{k l} \delta_{r s} n_{k} e_{k} B / p$, if $(r, k) \in\{00\} \times \mathcal{S},\left(\mathrm{L}^{B}\right)_{k l}^{r s}=\delta_{k l} \delta_{r s} \frac{5}{2} n_{k} e_{k} B / p$, if $(r, k) \in\{10\} \times \mathcal{S},\left(\mathrm{L}^{B}\right)_{k l}^{r s}=\delta_{k l} \delta_{r s}{\underset{c}{\text { int }}}_{k} n_{k} e_{k} B / k_{\mathrm{B}} p$, if $(r, k) \in\{00\} \times \mathcal{P}$, and $\mathcal{U}=\left(U,(0)_{k \in \mathcal{S}},(0)_{k \in \mathcal{P}}\right)^{t}$. The matrix $L$ is symmetric positive semi definite [14], the partial thermal conductivities are given by the scalar products

$$
\begin{align*}
\widehat{\lambda}^{\|} & =\frac{p}{T}\left\langle\alpha^{\widehat{\lambda}(1)}, \beta^{\widehat{\lambda}}\right\rangle=\frac{p}{T}\left(\left\langle\alpha^{10 \widehat{\lambda}(1)}, \beta^{10 \widehat{\lambda}}\right\rangle+\left\langle\alpha^{01 \widehat{\lambda}(1)}, \beta^{01 \widehat{\lambda}}\right\rangle\right),  \tag{77}\\
\widehat{\lambda}^{\perp}+\mathrm{i} \widehat{\lambda}^{\odot} & =\frac{p}{T}\left\langle\alpha^{\widehat{\lambda}(2)}, \beta^{\widehat{\lambda}}\right\rangle=\frac{p}{T}\left(\left\langle\alpha^{10 \widehat{\lambda}(2)}, \beta^{10 \widehat{\lambda}}\right\rangle+\left\langle\alpha^{01 \widehat{\lambda}(2)}, \beta^{01 \widehat{\lambda}}\right\rangle\right), \tag{78}
\end{align*}
$$

and, the thermal diffusion coefficients are given by

$$
\begin{align*}
\theta_{i}^{\|} & =-\left\langle\alpha^{\widehat{\lambda}(1)}, \beta^{D_{i}}\right\rangle=-\alpha_{i}^{00 \widehat{\lambda}(1)}  \tag{79}\\
\theta_{i}^{\perp}+\mathrm{i} \theta_{i}^{\odot} & =-\left\langle\alpha^{\widehat{\lambda}(2)}, \beta^{D_{i}}\right\rangle=-\alpha_{i}^{00 \widehat{\lambda}(2)} . \tag{80}
\end{align*}
$$

Note, however, that it is computationally more interesting to directly evaluate the thermal conductivities $\lambda^{\|}, \lambda^{\perp}, \lambda^{\odot}$ and the thermal diffusion ratios $\chi^{\|}, \chi^{\perp}, \chi^{\odot}$ rather than the partial thermal conductivities $\widehat{\lambda}^{\|}, \widehat{\lambda}^{\perp}, \widehat{\lambda}^{\odot}$ and the thermal diffusion coefficients $\theta^{\|}, \theta^{\perp}, \theta^{\odot}$, as described in the next section.

## 5 Thermal conductivity and thermal diffusion ratios

We first present the usual definition of the thermal conductivities $\lambda^{\|}, \lambda^{\perp}, \lambda^{\odot}$ and the thermal diffusion ratios $\chi^{\|}, \chi^{\perp}, \chi^{\odot}$. We then introduce a variational framework which allows a direct evaluation of these coefficients without the intermediate evaluations of the partial thermal conductivities $\widehat{\lambda}^{\|}, \widehat{\lambda}^{\perp}, \widehat{\lambda}^{\odot}$ and the thermal diffusion coefficients $\theta^{\|}, \theta^{\perp}, \theta^{\odot}$.

### 5.1 First definition of the thermal conductivities and the thermal diffusion ratios

The thermal diffusion ratios $\chi^{\|}=\left(\chi_{i}^{\|}\right)_{i \in \mathcal{S}}, \chi^{\perp}=\left(\chi_{i}^{\perp}\right)_{i \in \mathcal{S}}$, and $\chi^{\odot}=\left(\chi_{i}^{\odot}\right)_{i \in \mathcal{S}}$, are defined from the linear systems [25]

$$
\left\{\begin{array} { l } 
{ D ^ { \| } \chi ^ { \| } = \theta ^ { \| } , }  \tag{81}\\
{ \langle \chi ^ { \| } , U \rangle = 0 , }
\end{array} \quad \left\{\begin{array}{l}
\left(D^{\perp}+\mathrm{i} D^{\odot}\right)\left(\chi^{\perp}+\mathrm{i} \chi^{\odot}\right)=\theta^{\perp}+\mathrm{i} \theta^{\odot} \\
\left\langle\chi^{\perp}+\mathrm{i} \chi^{\odot}, U\right\rangle=0
\end{array}\right.\right.
$$

where $U$ is the vector of length $n^{s}$ with unit components $U=(1, \ldots, 1)^{t}$. Thanks to the symmetry of $D^{\|}, D^{\perp}$ and $D^{\odot}$, transposing these systems yields that the thermal diffusion ratios coincide with the modified thermal diffusion ratios $\widehat{\chi}^{\|}=\chi^{\|}, \widehat{\chi}^{\perp}=\chi^{\perp}$ and $\widehat{\chi}^{\odot}=\chi^{\odot}$ also introduced in [25]. We next define the thermal conductivities from [25]

$$
\begin{aligned}
\lambda^{\|} & =\widehat{\lambda}^{\|}-(p / T) \sum_{i, j \in \mathcal{S}} D_{j i}^{\|} \chi_{j}^{\|} \chi_{i}^{\|} \\
\lambda^{\perp}+\mathrm{i} \lambda^{\odot} & =\widehat{\lambda}^{\perp}+\mathrm{i} \hat{\lambda}^{\odot}-(p / T) \sum_{i, j \in \mathcal{S}}\left(D_{j i}^{\perp}+\mathrm{i} D_{j i}^{\odot}\right)\left(\chi_{j}^{\perp}+\mathrm{i} \chi_{j}^{\perp}\right)\left(\chi_{i}^{\perp}+\mathrm{i} \chi_{i}^{\odot}\right)
\end{aligned}
$$

The diffusion velocities and the heat flux can then be written

$$
\begin{align*}
& \boldsymbol{V}_{i}=-\sum_{j \in \mathcal{S}} D_{i j}^{\|}\left(\boldsymbol{d}_{j}^{\|}+\chi_{j}^{\|}\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\|}\right) \\
&-\sum_{j \in \mathcal{S}} D_{i j}^{\perp}\left(\boldsymbol{d}_{j}^{\perp}+\chi_{j}^{\perp}\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\perp}+\chi_{j}^{\odot}\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\odot}\right) \\
&-\sum_{j \in \mathcal{S}} D_{i j}^{\odot}\left(\boldsymbol{d}_{j}^{\odot}+\chi_{j}^{\perp}\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\odot}-\chi_{j}^{\odot}\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\perp}\right),  \tag{82}\\
& \boldsymbol{q}=\quad-\left(\lambda^{\|}\left(\boldsymbol{\partial}_{\boldsymbol{x}} T\right)^{\|}+\lambda^{\perp}\left(\boldsymbol{\partial}_{\boldsymbol{x}} T\right)^{\perp}+\lambda^{\odot}\left(\boldsymbol{\partial}_{\boldsymbol{x}} T\right)^{\odot}\right) \\
&+p \sum_{i \in \mathcal{S}}\left(\chi_{i}^{\|} \boldsymbol{V}_{i}^{\|}+\chi_{i}^{\perp} \boldsymbol{V}_{i}^{\perp}+\chi_{i}^{\odot} \boldsymbol{V}_{i}^{\odot}\right)+\sum_{i \in \mathcal{S}}\left(\frac{5}{2} k_{\mathrm{B}} T+\overline{\mathcal{E}_{i}}\right) n_{i} \boldsymbol{V}_{i} . \tag{83}
\end{align*}
$$

### 5.2 A variational framework for $\lambda$ and $\chi$

A variational framework for a direct evaluation of the thermal conductivity and the thermal diffusion ratios in a nonionized gas has been introduced in [14, 15]. This framework can readily be used for the transport properties parallel to the magnetic field $\lambda^{\|}$and $\chi^{\|}$. In this paper, we generalize this framework to the complex magnetized case for the perpendicular and transverse components $\lambda^{\perp}+\mathrm{i} \lambda^{\odot}$ and $\chi^{\perp}+\mathrm{i} \chi^{\odot}$. To this aim, we define

$$
\begin{equation*}
\varphi^{\lambda(1)}=\varphi^{\widehat{\lambda}(1)}+p k_{\mathrm{B}} T \sum_{j \in \mathcal{S}} \chi_{j}^{\|} \varphi^{D_{j}(1)}, \quad \varphi^{\lambda(2)}=\varphi^{\widehat{\lambda}(2)}+p k_{\mathrm{B}} T \sum_{j \in \mathcal{S}}\left(\chi_{j}^{\perp}+\mathrm{i} \chi^{\odot}\right) \varphi^{D_{j}(2)} \tag{84}
\end{equation*}
$$

$$
\begin{equation*}
\boldsymbol{\Psi}_{\|}^{\lambda}=\boldsymbol{\Psi}^{\widehat{\lambda}}+p k_{\mathrm{B}} T \sum_{j \in \mathcal{S}} \chi_{j}^{\|} \mathbf{\Psi}^{D_{j}}, \quad \boldsymbol{\Psi}_{\perp \odot}^{\lambda}=\boldsymbol{\Psi}^{\widehat{\lambda}}+p k_{\mathrm{B}} T \sum_{j \in \mathcal{S}}\left(\chi_{j}^{\perp}+\mathrm{i} \chi^{\odot}\right) \boldsymbol{\Psi}^{D_{j}} \tag{85}
\end{equation*}
$$

and it is easily shown that

$$
\begin{gather*}
\mathcal{F}^{\mathcal{S}}\left(\varphi^{\lambda(1)}\right)=\boldsymbol{\Psi}_{\|}^{\lambda}, \quad\left(\mathcal{F}^{\mathcal{S}}+\mathrm{i} B \mathcal{F}^{z, v}\right)\left(\boldsymbol{\varphi}^{\lambda(2)}\right)=\boldsymbol{\Psi}_{\perp \odot}^{\lambda},  \tag{86}\\
\left\langle\left\langle f^{0} \varphi^{\lambda(1)}, \psi^{l}\right\rangle\right\rangle=0, \quad\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\lambda(2)}, \psi^{l}\right\rangle\right\rangle=0, \quad l \in\left\{1, \ldots, n^{s}+4\right\} . \tag{87}
\end{gather*}
$$

From the definition of thermal diffusion ratios, it is straightforward to check that $\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\lambda(1)}, \Psi^{D_{j}}\right\rangle\right\rangle=$ 0 and $\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\lambda(2)}, \boldsymbol{\Psi}^{D_{j}}\right\rangle\right\rangle=0$ for $j \in \mathcal{S}$. However, the basis function $\phi^{1000 j}$ is a linear combination of $\boldsymbol{\Psi}^{D_{j}}$ and of the vector collisional invariant $\left(m_{k} \boldsymbol{C}_{k}\right)_{k \in \mathcal{S}}=\left(\left(m_{k}\left(\boldsymbol{c}_{k}-\boldsymbol{v}\right)\right)_{k \in \mathcal{S}}\right.$ in such a way that $\left\langle\left\langle f^{0} \varphi^{\lambda(1)}, \phi^{1000 j}\right\rangle\right\rangle=0$ and $\left\langle\left\langle f^{0} \varphi^{\lambda(2)}, \phi^{1000 j}\right\rangle\right\rangle=0$ for $j \in \mathcal{S}$. One may thus use a Galerkin variational approximation space orthogonal to the $\phi^{1000 j}, j \in \mathcal{S}$, in order to to solve (86)(87). It is important to observe then that for any basis function $\phi^{10 r k}$ orthogonal to $\phi^{1000 j}, j \in \mathcal{S}$, we have the relations $\left\langle\left\langle f^{0} \boldsymbol{\Psi}_{\|}^{\lambda}, \phi^{10 r k}\right\rangle\right\rangle=\left\langle\left\langle f^{0} \boldsymbol{\Psi}^{\widehat{\lambda}}, \phi^{10 r k}\right\rangle\right\rangle$ and $\left\langle\left\langle f^{0} \boldsymbol{\Psi}_{\perp \odot}^{\lambda}, \phi^{10 r k}\right\rangle\right\rangle=\left\langle\left\langle f^{0} \boldsymbol{\Psi}^{\widehat{\lambda}}, \phi^{10 r k}\right\rangle\right\rangle$ so that the transport linear systems associated with a Galerkin approximation of (86)(87) can readily be evaluated even though the thermal diffusion ratios are unknown. These orthogonality properties also imply that $\lambda^{\|}=\frac{1}{3 k_{B} T^{2}}\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\lambda(1)}, \boldsymbol{\Psi}_{\|}^{\lambda}\right\rangle\right\rangle=\frac{1}{3 k_{\mathrm{B}} T^{2}}\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\lambda(1)}, \boldsymbol{\Psi}^{\widehat{\lambda}}\right\rangle\right\rangle, \lambda^{\perp}+\mathrm{i} \lambda^{\odot}=\frac{1}{3 k_{\mathrm{B}} T^{2}}\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\lambda(2)}, \boldsymbol{\Psi}_{\perp \odot}^{\lambda}\right\rangle\right\rangle=$ $\frac{1}{3 k_{\mathrm{B}} T^{2}}\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\lambda(2)}, \boldsymbol{\Psi}^{\widehat{\lambda}}\right\rangle\right\rangle, \chi_{k}^{\|}=\frac{m_{k}}{3 p k_{\mathrm{B}} T}\left\langle\left\langle f^{0} \boldsymbol{\Psi}_{\|}^{\lambda}, \boldsymbol{\mathcal { C }}_{k}\right\rangle\right\rangle, \chi_{k}^{\perp}+\mathrm{i} \chi_{k}^{\odot}=\frac{m_{k}}{3 p k_{\mathrm{B}} T}\left\langle\left\langle f^{0} \boldsymbol{\Psi}_{\perp \odot}^{\lambda}, \boldsymbol{\mathcal { C }}_{k}\right\rangle\right\rangle$, where $\boldsymbol{\mathcal { C }}_{k}=\left(\boldsymbol{C}_{k} \delta_{i k}\right)_{i \in \mathcal{S}}$, so that

$$
\begin{gather*}
\lambda^{\|}=\frac{1}{3 k_{\mathrm{B}} T^{2}} \llbracket \varphi^{\lambda(1)}, \boldsymbol{\varphi}^{\lambda(1)} \rrbracket, \quad \lambda^{\perp}+\mathrm{i} \lambda^{\odot}=\frac{1}{3 k_{\mathrm{B}} T^{2}}\left(\llbracket \boldsymbol{\varphi}^{\lambda(2)}, \boldsymbol{\varphi}^{\lambda(2)} \rrbracket-\left(\left(\boldsymbol{\varphi}^{\lambda(2)}, \boldsymbol{\varphi}^{\lambda(2)}\right)\right)\right),  \tag{88}\\
\chi_{k}^{\|}=\frac{m_{k}}{3 p k_{\mathrm{B}} T} \llbracket \varphi^{\lambda(1)}, \boldsymbol{e}_{k} \rrbracket, \quad \chi \frac{1}{k}+\mathrm{i} \chi_{k}^{\odot}=\frac{m_{k}}{3 p k_{\mathrm{B}} T} \llbracket \boldsymbol{\varphi}^{\lambda(2)}, \boldsymbol{e}_{k} \rrbracket . \tag{89}
\end{gather*}
$$

### 5.3 Transport linear systems associated with $\lambda, \chi$

The vector integral equations associated with the thermal conductivity and the thermal diffusion ratios coefficients are in the form $\left(\mathcal{F}^{\mathcal{S}}+\delta_{21} B \mathcal{F}^{z, v}\right)\left(\varphi^{\lambda(I)}\right)=\boldsymbol{\Psi}^{\lambda(I)}$, with I $=1,2$. Since we already know that $\varphi^{\lambda(I)}, I=1,2$, are orthogonal to $\phi^{1000 k}, k \in \mathcal{S}$, the variational approximation space $\mathcal{A}^{\lambda}$ to be considered in the first place is the space spanned by $\phi^{1010 k}, k \in \mathcal{S}$, and $\phi^{1001 k}, k \in \mathcal{P}$.

For convenience, $\varphi^{\lambda(1)}$ is taken in the form

$$
\varphi^{\lambda(\mathrm{I})}=\sqrt{2 k_{\mathrm{B}} T}\left(\sum_{k \in \mathcal{S}} \sqrt{m_{k}} \alpha_{k}^{10 \lambda(\mathrm{I})} \phi^{1010 k}+\sum_{k \in \mathcal{P}} \sqrt{m_{k}} \alpha_{k}^{01 \lambda(\mathrm{I})} \phi^{1001 k}\right), \quad \mathrm{I}=1,2
$$

The matrix associated with the variational procedure is denoted by $\Lambda$ and is rescaled such that $\Lambda_{k l}^{r s}=$ $\left(2 \sqrt{m_{k} m_{l}} / 3 p\right) \llbracket \phi^{10 r k}, \phi^{10 s l} \rrbracket,(r, k),(s, l) \in\{10\} \times \mathcal{S} \cup\{01\} \times \mathcal{P}$. It is then important to observe that $\beta_{k}^{r \lambda}=\sqrt{2 m_{k} / k_{\mathrm{B}} T} / 3 p\left\langle\left\langle f^{0} \phi^{10 r k}, \Psi^{\widehat{\lambda}}\right\rangle\right\rangle$, so that $\beta_{k}^{r \lambda}=\beta_{k}^{r \widehat{\lambda}}$ for $(r, k) \in\{10\} \times \mathcal{S} \cup\{01\} \times \mathcal{P}$. We then have $\Lambda \in \mathbb{R}^{n^{s}+n^{p}, n^{s}+n^{p}}, \beta^{\lambda} \in \mathbb{R}^{n^{s}+n^{p}}$, and the linear systems for $\alpha^{\lambda(1)} \in \mathbb{R}^{n^{s}+n^{p}}$ and $\alpha^{\lambda(2)} \in \mathbb{C}^{n^{s}+n^{p}}$ are in the form

$$
\Lambda \alpha^{\lambda(1)}=\beta^{\lambda}, \quad\left(\Lambda+\mathrm{i} \Lambda^{B}\right) \alpha^{\eta(2)}=\beta^{\lambda},
$$

where $\Lambda^{B}$ is the diagonal matrix given by $\left(\Lambda^{B}\right)_{k l}^{r s}=\delta_{k l} \delta_{r s} \frac{5}{2} n_{k} e_{k} B / p$, for $(r, k) \in\{10\} \times \mathcal{S}$ and $\left(\Lambda^{B}\right)_{k l}^{r s}=$ $\delta_{k l} \delta_{r s} \mathfrak{c}_{k}^{\mathrm{int}} n_{k} e_{k} B / k_{\mathrm{B}} p$, for $(r, k) \in\{01\} \times \mathcal{P}$. The coefficients of the matrix $\Lambda$ are intricated expressions that can be written in the form [14]

$$
\begin{aligned}
& \Lambda_{k k}^{1010}=\sum_{\substack{l \in \mathcal{S} \\
l \neq k}} \frac{X_{k} X_{l}}{\mathcal{D}_{k l}} \frac{m_{k} m_{l}}{\left(m_{k}+m_{l}\right)^{2}}\left[\frac{15}{2} \frac{m_{k}}{m_{l}}+\frac{25}{4} \frac{m_{l}}{m_{k}}-3 \frac{m_{l}}{m_{k}} \bar{B}_{k l}+4 \bar{A}_{k l}\right. \\
& \left.+\frac{25}{12} \frac{\left\lfloor\left(\Delta \epsilon_{k l}\right)^{2} \rrbracket_{k l}\right.}{\Omega_{k l}^{(1,1)}}\right]+\frac{X_{k}^{2}}{2 \mathcal{D}_{k k}}\left[4 \bar{A}_{k k}+\frac{25}{12} \frac{\left\lfloor\left(\Delta \epsilon_{k k}\right)^{2} \rrbracket_{k k}\right.}{\Omega_{k k}^{(1,1)}}\right], \quad k \in \mathcal{S}, \\
& \Lambda_{k l}^{1010}=-\frac{X_{k} X_{l}}{\mathcal{D}_{k l}} \frac{m_{k} m_{l}}{\left(m_{k}+m_{l}\right)^{2}}\left[\frac{55}{4}-3 \bar{B}_{k l}-4 \bar{A}_{k l}-\frac{25}{12} \frac{\|\left(\Delta \epsilon_{k l}\right)^{2} \rrbracket_{k l}}{\Omega_{k l}^{(1,1)}}\right], \quad k, l \in \mathcal{S}, k \neq l,
\end{aligned}
$$

$$
\begin{aligned}
& \Lambda_{k k}^{1001}=-\sum_{\substack{l \in \mathcal{S} \\
l \neq k}} \frac{X_{k} X_{l}}{\mathcal{D}_{k l}} \frac{m_{k}}{m_{k}+m_{l}}\left[\frac{5}{4} \frac{\llbracket \Delta \epsilon_{k} \Delta \epsilon_{k l} \rrbracket_{k l}}{\Omega_{k l}^{(1,1)}}+\frac{5}{2} \frac{m_{l}}{m_{k}} \frac{\llbracket \epsilon_{k K}^{0}\left(\gamma^{2}-\gamma \gamma^{\prime} \cos \chi\right) \rrbracket_{k l}}{\Omega_{k l}^{(1,1)}}\right. \\
& \left.-\frac{m_{l}}{m_{k}} \frac{\llbracket \epsilon_{k K}^{0}\left(\gamma^{4}-\gamma \gamma^{\prime 3} \cos \chi\right) \rrbracket_{k l}}{\Omega_{k l}^{(1,1)}}\right]-\frac{5}{8} \frac{X_{k}^{2}}{\mathcal{D}_{k k}} \frac{\llbracket\left(\Delta \epsilon_{k k}\right)^{2} \rrbracket_{k k}}{\Omega_{k k}^{(1,1)}}, \quad k \in \mathcal{P}, \\
& \Lambda_{k l}^{1001}=\frac{X_{k} X_{l}}{\mathcal{D}_{k l}} \frac{m_{l}}{m_{k}+m_{l}}\left[-\frac{5}{4} \frac{\llbracket \widetilde{\Delta} \epsilon_{l} \Delta \epsilon_{k l} \rrbracket_{k l}}{\Omega_{k l}^{(1,1)}}+\frac{5}{2} \frac{\llbracket \epsilon_{l L}^{0}\left(\gamma^{2}-\gamma \gamma^{\prime} \cos \chi\right) \rrbracket_{k l}}{\Omega_{k l}^{(1,1)}}\right. \\
& \left.-\frac{\llbracket \epsilon_{l C_{L}}^{0}\left(\gamma^{4}-\gamma \gamma^{\prime 3} \cos \chi\right) \rrbracket_{k l}}{\Omega_{k l}^{(1,1)}}\right], \quad k \in \mathcal{S}, \quad l \in \mathcal{P}, k \neq l, \\
& \Lambda_{k k}^{0101}=\sum_{\substack{l \in \mathcal{S} \\
l \neq k}} X_{k} X_{l}\left[\frac{\mathfrak{c}_{k}^{\mathrm{int}}}{k_{\mathrm{B}} \mathcal{D}_{k \text { int }, l}}+\frac{3}{4} \frac{m_{k}}{m_{l}} \frac{\llbracket\left(\Delta \epsilon_{k}\right)^{2} \rrbracket_{k l}}{\Omega_{k l}^{(1,1)} \mathcal{D}_{k l}}\right] \\
& +X_{k}^{2}\left[\frac{\mathfrak{c}_{k}^{\text {int }}}{k_{\mathrm{B}} \mathcal{D}_{k \text { int }, k}}+\frac{3}{8} \frac{\left\lfloor\left(\Delta \epsilon_{k k}\right)^{2} \rrbracket_{k k}\right.}{\Omega_{k k}^{(1,1)} \mathcal{D}_{k k}}\right], \quad k \in \mathcal{P}, \\
& \Lambda_{k l}^{0101}=-X_{k} X_{l}\left[\frac{\llbracket \epsilon_{k K}^{0}\left(\epsilon_{l L}^{0} \gamma^{2}-\epsilon_{l L^{\prime}}^{0} \gamma \gamma^{\prime} \cos \chi\right) \rrbracket_{k l}}{\Omega_{k l}^{(1,1)} \mathcal{D}_{k l}}-\frac{3}{4} \frac{\llbracket \Delta \epsilon_{k} \widetilde{\Delta} \epsilon_{l} \rrbracket_{k l}}{\Omega_{k l}^{(1,1)} \mathcal{D}_{k l}}\right], \quad k, l \in \mathcal{P}, k \neq l,
\end{aligned}
$$

where $\|\cdot\|_{k l}$ is an averaging operator associated with collisions between the species pair $(k, l)$. The details of the corresponding collision integrals are omitted for brevity and we refer to [14] for more details. The matrix $\Lambda$ is symmetric positive definite [14] and the thermal conductivities are given by the following scalar products

$$
\begin{align*}
\lambda^{\|} & =\frac{p}{T}\left\langle\alpha^{\lambda(1)}, \beta^{\lambda}\right\rangle=\frac{p}{T}\left(\left\langle\alpha^{10 \lambda(1)}, \beta^{10 \lambda}\right\rangle+\left\langle\alpha^{01 \lambda(1)}, \beta^{01 \lambda}\right\rangle\right)  \tag{90}\\
\lambda^{\perp}+\mathrm{i} \lambda^{\odot} & =\frac{p}{T}\left\langle\alpha^{\lambda(2)}, \beta^{\lambda}\right\rangle=\frac{p}{T}\left(\left\langle\alpha^{10 \lambda(2)}, \beta^{10 \lambda}\right\rangle+\left\langle\alpha^{01 \lambda(2)}, \beta^{01 \lambda}\right\rangle\right) \tag{91}
\end{align*}
$$

and the thermal diffusion ratios by

$$
\begin{equation*}
\chi^{\|}=L^{00 \lambda} \alpha^{\widehat{\lambda}(1)}, \quad \chi^{\perp}+\mathrm{i} \chi^{\odot}=L^{00 \lambda} \alpha_{i}^{00 \widehat{\lambda}(2)}, \tag{92}
\end{equation*}
$$

where $L^{00 \lambda}$ is the upper right block of $L$ of size $n^{s} \times\left(n^{s}+n^{p}\right)$ in such a way that the matrix $L$ has the bloc decomposition

$$
L=\left(\begin{array}{cc}
L^{0000} & L^{00 \lambda}  \tag{93}\\
L^{\lambda 00} & L^{\lambda \lambda}
\end{array}\right)=\left(\begin{array}{cc}
\Delta_{[00]} & L^{00 \lambda} \\
L^{\lambda 00} & \Lambda
\end{array}\right) .
$$

The matrix $L^{00 \lambda}$ can be written $L^{00 \lambda}=\left(L^{0010}, L^{0001}\right)$ where the blocks $L^{0010}$ and $L^{0001}$ are given by

$$
\begin{align*}
L_{k k}^{0010} & =-\sum_{\substack{l \in \mathcal{S} \\
l \neq k}} \frac{X_{k} X_{l}}{2 \mathcal{D}_{k l}} \frac{m_{l}}{m_{k}+m_{l}}\left(6 \bar{C}_{k l}-5\right), \quad k \in \mathcal{S},  \tag{94}\\
L_{k l}^{0010} & =\frac{X_{k} X_{l}}{2 \mathcal{D}_{k l}} \frac{m_{k}}{m_{k}+m_{l}}\left(6 \bar{c}_{k l}-5\right), \quad k, l \in \mathcal{S}, \quad k \neq l, \\
L_{k k}^{0001} & =-\sum_{\substack{l \in \mathcal{S} \\
l \neq k}} X_{k} X_{l} \frac{\| \epsilon_{k K}^{0}\left(\gamma^{2}-\gamma \gamma^{\prime} \cos \chi\right) \rrbracket_{k l}}{\Omega_{k l}^{(1,1)} \mathcal{D}_{k l}}, \quad k \in \mathcal{P}, \\
L_{k l}^{0001} & =X_{k} X_{l} \frac{\| \epsilon_{l L}^{0}\left(\gamma^{2}-\gamma \gamma^{\prime} \cos \chi\right) \rrbracket_{k l}}{\Omega_{k l}^{(1,1)} \mathcal{D}_{k l}}, \quad k \in \mathcal{S}, \quad l \in \mathcal{P}, \quad k \neq l .
\end{align*}
$$

From the expression of the matricies $L, \Lambda$, or $L^{00 \lambda}$, we note that, in addition to the classical $\Omega_{k l}^{(i, j)}$ integrals, many collision integrals associated with internal energy exchanges are required for the evaluation of transport properties of polyatomic species mixtures. These collision integrals are discussed in particular in $[5,14,34]$ as well as some typical approximations like those of Mason and Monchick in terms of relaxation times. In order to solve the transport linear systems associated with the thermal conductivity we recommend a few step of an orthogonal error method preconditioned by the diagonal matrix $\operatorname{diag}(\Lambda)+\mathrm{i} \Lambda^{B}[14,16]$. The thermal diffusion ratios are then readily evaluated from (92).

In our numerical simulations for air at 10000 K , the relaxation times for internal energy of the polyatomic neutral molecules have been estimated as described in [14] whereas the the rotational relaxation times for internal energy of the polyatomic ionized molecules have been approximated as the relaxation time of the corresponding neutral molecules [1]. Our numerical simulations with weakly ionized air have shown that three iterations are generally required in order to evaluate the thermal diffusion ratios with a good accuracy, whereas two iterates are generally sufficient for the thermal conductivities.

It is also possible to use a reduced linear system associated with the total energy vector functionals $\phi^{10 e k}, k \in \mathcal{S}$, defined by $\phi^{10 e k}=\phi^{1010 k}+\phi^{1001 k}$ if $k \in \mathcal{P}$, and $\phi^{10 e k}=\phi^{1010 k}$ for monatomic species $k \in \mathcal{S} \backslash \mathcal{P}$. The corresponding reduced linear systems of size $n^{s}$ are associated with the matrices $\Lambda_{[e]}$ and $\Lambda_{[e]}+\mathrm{i} \Lambda_{[e]}^{B}$, where $\Lambda_{[e]}$ is explicited in $[14,15]$ and where $\Lambda_{[e]}^{B}$ is the diagonal matrix defined by $\Lambda_{[e] k k}^{B}=\mathfrak{c}_{p k} n_{k} e_{k} B / p, k \in \mathcal{S}$. These reduced linear systems generally yield accurate results at lower computational costs. For weakly ionized air at high temperature we have found that the reduced thermal conductivities are usually within one percent of the more accurate conductivity whereas the thermal diffusion ratios are only accurate within ten percents.

### 5.4 Stefan-Maxwell equations with Soret effect

Stefan-Maxwell equations associated with the real vector $\mathcal{V} \|$ whose $n^{s}$ first components are the diffusion velocities parallel to the magnetic field $\boldsymbol{V}^{\|}=\mathcal{V}^{00 \|}=\Pi \mathcal{V}^{\|}$are similar to that of non-ionized mixtures already investigated in $[23,14]$. We thus only discuss in the following the generalized Stefan-Maxwell equations associated with the complex vector $\mathcal{V}^{\perp}-\mathrm{i} \mathcal{V}^{\odot}$ defined by

$$
\mathcal{V}^{\perp}-\mathrm{i} \mathcal{V}^{\odot}=\sum_{j \in \mathcal{S}} \alpha^{D_{j}(2)}\left(\left(\boldsymbol{d}_{j}^{\perp}-\mathrm{i} \boldsymbol{d}_{j}^{\odot}\right)+\left(\chi_{j}^{\perp}+\mathrm{i} \chi_{j}^{\odot}\right)\left(\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\perp}-\mathrm{i}\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\odot}\right)\right)
$$

whose $n^{s}$ first components are the diffusion velocities perpendicular and transverse to the magnetic field $\boldsymbol{V}^{\perp}-\mathrm{i} \boldsymbol{V}^{\odot}=\mathcal{V}^{00 \perp}-\mathrm{i} \mathcal{V}^{00 \odot}=\Pi\left(\mathcal{V}^{\perp}-\mathrm{i} \mathcal{V}^{\odot}\right)$.

The Stefan-Maxwell equations in the presence of Soret effect are more conveniently written in terms of thermal diffusion ratios [38, 21, 9, 24]. Multiplying the transport linear system (72) for $\alpha^{D_{j}(2)}$ by the vector $\boldsymbol{d}_{j}^{\perp}-\boldsymbol{d}_{j}^{\odot}+\left(\chi_{j}^{\perp}+\mathrm{i} \chi_{j}^{\odot}\right)\left(\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log t\right)^{\perp}-\mathrm{i}\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log t\right)^{\odot}\right)$ we obtain the proper generalization to the complex framework of the Stefan-Maxwell equations with Soret effect

$$
\begin{equation*}
\left(L+\mathrm{i} L^{B}\right)\left(\mathcal{V}^{\perp}-\mathrm{i} \mathcal{V}^{\odot}\right)=\sum_{j \in \mathcal{S}} \beta^{D_{j}}\left(\left(\boldsymbol{d}_{j}^{\perp}-\mathrm{i} \boldsymbol{d}_{j}^{\odot}\right)+\left(\chi_{j}^{\perp}+\mathrm{i} \chi_{j}^{\odot}\right)\left(\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\perp}-\mathrm{i}\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\odot}\right)\right) \tag{95}
\end{equation*}
$$

Upon introducing the Schur complement

$$
\Delta+\mathrm{i} \Delta^{B}=\Delta_{[00]}+\mathrm{i} \Delta_{[00]}^{B}-L^{00 \lambda}\left(L^{\lambda \lambda}+\mathrm{i} \Lambda^{B}\right)^{-1} L^{\lambda 00}
$$

the Stefan-Maxwell equations can also be rewritten in the form

$$
\begin{equation*}
\left(\Delta+\mathrm{i} \Delta^{B}\right)\left(\boldsymbol{V}^{\perp}-\mathrm{i} \boldsymbol{V}^{\odot}\right)=\tilde{\boldsymbol{d}}^{\perp}-\mathrm{i} \widetilde{\boldsymbol{d}}^{\odot}+\left(\chi^{\perp}+\mathrm{i} \chi^{\odot}\right)\left(\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\perp}-\mathrm{i}\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\odot}\right) \tag{96}
\end{equation*}
$$

where $\boldsymbol{V}^{\diamond}=\mathcal{V}^{00 \diamond}=\Pi \mathcal{V}^{\diamond}, \chi^{\diamond}=\left(\chi_{1}^{\diamond}, \ldots, \chi_{n^{s}}^{\diamond}\right)^{t}, \diamond \in\{\|, \perp, \odot\}$, and

$$
\begin{equation*}
\tilde{\boldsymbol{d}}^{\perp}-\tilde{\mathrm{i}}^{\odot}=\sum_{j \in \mathcal{S}} \beta^{00 D_{j}}\left(\boldsymbol{d}_{j}^{\perp}-\mathrm{i} \boldsymbol{d}_{j}^{\odot}\right)=\boldsymbol{d}^{\perp}-\mathrm{i} \boldsymbol{d}^{\odot}-Y \sum_{j \in \mathcal{S}}\left(\boldsymbol{d}_{j}^{\perp}-\mathrm{i} \boldsymbol{d}_{j}^{\odot}\right) \tag{97}
\end{equation*}
$$

are the unconstrained diffusion driving forces. These equations may be approximated as

$$
\begin{equation*}
\left(\Delta_{[00]}+\mathrm{i} \Delta_{[00]}^{B}\right)\left(\boldsymbol{V}^{\perp}-\mathrm{i} \boldsymbol{V}^{\odot}\right)=\tilde{\boldsymbol{d}}^{\perp}-\mathrm{i} \tilde{\boldsymbol{d}}^{\odot}+\left(\chi^{\perp}+\mathrm{i} \chi^{\odot}\right)\left(\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\perp}-\mathrm{i}\left(\boldsymbol{\partial}_{\boldsymbol{x}} \log T\right)^{\odot}\right), \tag{98}
\end{equation*}
$$

depending on the accuracy of the first order diffusion matrices. Projected standard iterative techniques as well as projected generalized conjugate gradient methods can be used to solve the Stefan-Maxwell equations with or without Soret effect and with or without magnetic field effects [14, 17, 27].

## 6 Dependence of transport coefficients on the magnetic field

From a theoretical and computational point of view, it is important to investigate the behavior of transport coefficients and transport fluxes for vanishing magnetic fields. In this section we establish the proper structural properties of the transport coefficients which guarantee that all transport fluxes behave smoothly as $\boldsymbol{B}$ goes to zero.

### 6.1 Heat and mass transport coefficients

The operators $\mathcal{F}^{\mathcal{S}}$ and $\mathcal{F}^{z, v}$ do not depend on the magnetic field $\boldsymbol{B}$ so that the functions $\varphi_{i}^{\widehat{\lambda}(1)}, i \in \mathcal{S}$, and $\varphi_{i}^{D_{j}(1)}, i, j \in \mathcal{S}$, are independent of $\boldsymbol{B}$. On the other hand, in order to investigate the dependence on the magnetic field $\boldsymbol{B}$ of the perpendicular and transverse transport coefficients we expand the functions $\varphi^{\widehat{\lambda}(2)}$, and $\varphi^{D_{j}(2)}, j \in \mathcal{S}$, in series of the intensity of the magnetic field $B=\|\boldsymbol{B}\|$. More specifically, we write

$$
\begin{equation*}
\boldsymbol{\varphi}_{i}^{\widehat{\lambda}(2)}=\sum_{n \in \mathbb{N}}(\mathrm{i} B)^{n} \boldsymbol{\varphi}_{i, n}^{\widehat{\lambda}}, \quad \boldsymbol{\varphi}_{i}^{D_{j}(2)}=\sum_{n \in \mathbb{N}}(\mathrm{i} B)^{n} \boldsymbol{\varphi}_{i, n}^{D_{j}}, \quad i, j \in \mathcal{S}, \tag{99}
\end{equation*}
$$

where the functions $\varphi_{\cdot, n}^{\widehat{\lambda}}=\left(\boldsymbol{\varphi}_{i, n}^{\widehat{\lambda}}\right)_{i \in \mathcal{S}}, \varphi_{\cdot, n}^{D_{j}}=\left(\boldsymbol{\varphi}_{i, n}^{D_{j}}\right)_{i \in \mathcal{S}}, j \in \mathcal{S}, n \in \mathbb{N}$, do not depend on the magnetic field and satisfy the integro-differential equations

$$
\begin{gather*}
\mathcal{F}^{\mathcal{S}}\left(\boldsymbol{\varphi}_{\cdot, 0}^{\widehat{\lambda}}\right)=\boldsymbol{\Psi}^{\widehat{\lambda}}, \quad \mathcal{F}^{\mathcal{S}}\left(\boldsymbol{\varphi}_{\cdot, n+1}^{\widehat{\lambda}}\right)=-\mathcal{F}^{z, v}\left(\boldsymbol{\varphi}_{\cdot, n}^{\widehat{\lambda}}\right), \quad n \geq 0,  \tag{100}\\
\mathcal{F}^{\mathcal{S}}\left(\boldsymbol{\varphi}_{\cdot, 0}^{D_{j}}\right)=\boldsymbol{\Psi}^{D_{j}}, \quad \mathcal{F}^{\mathcal{S}}\left(\boldsymbol{\varphi}_{\cdot, n+1}^{D_{j}}\right)=-\mathcal{F}^{z, v}\left(\boldsymbol{\varphi}_{\cdot, n}^{D_{j}}\right), \quad n \geq 0, \quad j \in \mathcal{S}, \tag{101}
\end{gather*}
$$

and the scalar constraints

$$
\begin{equation*}
\left\langle\left\langle f^{0} \varphi_{\cdot, n}^{\widehat{\lambda}}, \psi^{l}\right\rangle\right\rangle=0, \quad\left\langle\left\langle f^{0} \varphi_{\cdot, n}^{D_{j}}, \psi^{l}\right\rangle\right\rangle=0, \quad n \geq 0, \quad l \in\left\{0, \ldots, n^{s}+4\right\} \tag{102}
\end{equation*}
$$

These equations yield existence and uniqueness for $\boldsymbol{\varphi}_{i, n}^{\widehat{\lambda}}, \boldsymbol{\varphi}_{i, n}^{D_{j}}, i, j \in \mathcal{S}, n \in \mathbb{N}$. From the well posedness of the integral operator, the radius of convergence of these series is nonzero and we also remark that $\boldsymbol{\varphi}_{i, 0}^{\widehat{\lambda}}=\boldsymbol{\varphi}_{i}^{\widehat{\lambda}(1)}$ and $\boldsymbol{\varphi}_{i, 0}^{D_{j}}=\boldsymbol{\varphi}_{i}^{D_{j}(1)}, i, j \in \mathcal{S}$. From these series expansions, we can further expand the transport coefficients $D_{i j}^{\|}, D_{i j}^{\perp}$ and $D_{i j}^{\odot}, i, j \in \mathcal{S}$, in the form

$$
\begin{equation*}
D_{i j}^{\|}=D_{i j}^{0}, \quad D_{i j}^{\perp}=\sum_{N \in \mathbb{N}} B^{2 N} D_{i j}^{2 N}, \quad D_{i j}^{\odot}=\sum_{N \in \mathbb{N}} B^{2 N+1} D_{i j}^{2 N+1} \tag{103}
\end{equation*}
$$

where the coefficients $D_{i j}^{M}, i, j \in \mathcal{S}, M \in \mathbb{N}$, do not depend on the magnetic field and are given by

$$
D_{i j}^{M}=(-1)^{\left[\frac{M}{2}\right]} \frac{1}{3} p k_{\mathrm{B}} T\left(\sum_{n+m=M}(-1)^{n} \llbracket \boldsymbol{\varphi}_{\cdot, n}^{D_{i}}, \boldsymbol{\varphi}_{\cdot, m}^{D_{j}} \rrbracket-\sum_{n+m=M-1}(-1)^{n}\left(\left(\boldsymbol{\varphi}_{\cdot, n}^{D_{i}}, \boldsymbol{\varphi}_{\cdot, m}^{D_{j}}\right)\right)\right) .
$$

We then deduce the existence of regular functions denoted by $\phi_{i j}^{\perp}, \phi_{i j}^{\odot}, i, j \in \mathcal{S}$, so that

$$
\begin{equation*}
D_{i j}^{\perp}-D_{i j}^{\|}=B^{2} \phi_{i j}^{\perp}\left(B^{2}\right), \quad D_{i j}^{\odot}=B \phi_{i j}^{\odot}\left(B^{2}\right) \tag{104}
\end{equation*}
$$

The above expansion can be followed through for the coefficients $\theta_{i}^{\|}, \theta_{i}^{\perp}$, and $\theta_{i}^{\odot}, i \in \mathcal{S}$, by using expansions (99) for the functions $\varphi_{i}^{\widehat{\lambda}(2)}, i \in \mathcal{S}$. More specifically, we obtain

$$
\begin{equation*}
\theta_{i}^{\|}=\theta_{i}^{0}, \quad \theta_{i}^{\perp}=\sum_{N \in \mathbb{N}} B^{2 N} \theta_{i}^{2 N}, \quad \theta_{i}^{\odot}=\sum_{N \in \mathbb{N}} B^{2 N+1} \theta_{i}^{2 N+1} \tag{105}
\end{equation*}
$$

where the coefficients $\theta_{i}^{N}, i \in \mathcal{S}, N \in \mathbb{N}$, do not depend on the magnetic field and are defined by

$$
\theta_{i}^{2 N}=\frac{1}{3}(-1)^{\left[\frac{M}{2}\right]+1}\left(\sum_{n+m=M}(-1)^{n} \llbracket \boldsymbol{\varphi}_{\cdot, n}^{D_{i}}, \boldsymbol{\varphi}_{\cdot, m}^{\widehat{\lambda}} \rrbracket-\sum_{n+m=M-1}(-1)^{n}\left(\left(\boldsymbol{\varphi}_{\cdot, n}^{D_{i}}, \boldsymbol{\varphi}_{\cdot, m}^{\widehat{\lambda}}\right)\right)\right),
$$

and we then deduce the existence of regular functions denoted by $\vartheta_{i}^{\perp}, \vartheta_{i}^{\odot}, i \in \mathcal{S}$, so that

$$
\begin{equation*}
\theta_{i}^{\perp}-\theta_{i}^{\|}=B^{2} \vartheta_{i}^{\perp}\left(B^{2}\right), \quad \theta_{i}^{\odot}=B \vartheta_{i}^{\odot}\left(B^{2}\right) \tag{106}
\end{equation*}
$$

By using expansions (99) for the functions $\boldsymbol{\varphi}_{i}^{\widehat{\lambda}(2)}, i \in \mathcal{S}$, we expand the transport coefficients $\widehat{\lambda}^{\|}$, $\widehat{\lambda}^{\perp}, \widehat{\lambda}^{\odot}$, in the form

$$
\begin{equation*}
\widehat{\lambda}^{\|}=\widehat{\lambda}^{0}, \quad \widehat{\lambda}^{\perp}=\sum_{N \in \mathbb{N}} B^{2 N} \widehat{\lambda}^{2 N}, \quad \hat{\lambda}^{\odot}=\sum_{N \in \mathbb{N}} B^{2 N+1} \widehat{\lambda}^{2 N+1} \tag{107}
\end{equation*}
$$

where the coefficients $\widehat{\lambda}^{M}, M \in \mathbb{N}$, do not depend on the magnetic field and are given by

$$
\widehat{\lambda}^{M}=(-1)^{\left[\frac{M}{2}\right]} \frac{1}{3 k_{\mathrm{B}} T^{2}}\left(\sum_{n+m=M}(-1)^{n} \llbracket \boldsymbol{\varphi}_{\cdot, n}^{\widehat{\lambda}}, \boldsymbol{\varphi}_{\cdot, m}^{\widehat{\lambda}} \rrbracket-\sum_{n+m=M-1}(-1)^{n}\left(\left(\boldsymbol{\varphi}_{\cdot, n}^{\widehat{\lambda}}, \boldsymbol{\varphi}_{\cdot, m}^{\widehat{\lambda}}\right)\right)\right)
$$

We then deduce the existence of regular functions denoted by $\hat{\varsigma}^{\perp}, \hat{\varsigma}^{\ominus}$, so that

$$
\begin{equation*}
\widehat{\lambda}^{\perp}-\widehat{\lambda}^{\|}=B^{2} \hat{\varsigma}^{\perp}\left(B^{2}\right), \quad \widehat{\lambda}^{\odot}=B \hat{\varsigma}^{\odot}\left(B^{2}\right) \tag{108}
\end{equation*}
$$

An expanded form for coefficients $\chi_{i}^{\|}, \chi_{i}^{\perp}, \chi_{i}^{\odot}, i \in \mathcal{S}$, can be deduced from expressions (103) and (105)

$$
\begin{equation*}
\chi_{i}^{\|}=\chi_{i}^{0}, \quad \chi_{i}^{\perp}=\sum_{N \in \mathbb{N}} B^{2 N} \chi_{i}^{2 N}, \quad \chi_{i}^{\odot}=\sum_{N \in \mathbb{N}} B^{2 N+1} \chi_{i}^{2 N+1} \tag{109}
\end{equation*}
$$

where the coefficients $\chi_{i}, i \in \mathcal{S}, N \in \mathbb{N}$, are defined by the recursive systems

$$
\sum_{j \in \mathcal{S}} D_{i j}^{0} \chi_{j}^{N}=\theta_{i}^{N}-\sum_{n=0}^{N-1}(-1)^{n(N+1)} \sum_{j \in \mathcal{S}} D_{i j}^{N-n} \chi_{j}^{n}, \quad i \in \mathcal{S}, \quad \sum_{j \in \mathcal{S}} \chi_{j}^{N}=0
$$

We thus deduce the existence of regular functions denoted by $\psi_{i}^{\perp}, \psi_{i}^{\odot}, i \in \mathcal{S}$, so that

$$
\begin{equation*}
\chi_{i}^{\perp}-\chi_{i}^{\|}=B^{2} \psi_{i}^{\perp}\left(B^{2}\right), \quad \chi_{i}^{\odot}=B \psi_{i}^{\odot}\left(B^{2}\right) \tag{110}
\end{equation*}
$$

Finally, the coefficients $\lambda^{\|}, \lambda^{\perp}$ and $\lambda^{\odot}$ are easily shown to satisfy properties identical to that of the coefficients $\widehat{\lambda} \|, \widehat{\lambda}^{\perp}$ and $\widehat{\lambda}^{\odot}$.

On the other hand, upon introducing the tensorial transport coefficients $\boldsymbol{D}_{i j}, i, j \in \mathcal{S}, \boldsymbol{\theta}_{i}, i \in \mathcal{S}$, and $\widehat{\boldsymbol{\lambda}}$ defined by

$$
\begin{aligned}
\boldsymbol{D}_{i j} & =D_{i j}^{\|} \mathbf{M}^{\|}+D_{i j}^{\perp} \mathbf{M}^{\perp}+D_{i j}^{\odot} \mathbf{M}^{\odot} \\
\boldsymbol{\theta}_{i} & =\theta_{i}^{\|} \mathbf{M}^{\|}+\theta_{i}^{\perp} \mathbf{M}^{\perp}+\theta_{i}^{\odot} \mathbf{M}^{\odot} \\
\widehat{\boldsymbol{\lambda}} & =\widehat{\lambda}^{\|} \mathbf{M}^{\|}+\widehat{\lambda}^{\perp} \mathbf{M}^{\perp}+\widehat{\lambda}^{\odot} \mathbf{M}^{\odot}
\end{aligned}
$$

where $\mathbf{M}^{\|}=\mathcal{B} \otimes \mathcal{B}, \mathbf{M}^{\perp}=\boldsymbol{I}-\mathcal{B} \otimes \mathcal{B}$, and $\mathbf{M}^{\odot}=\boldsymbol{R}(\mathcal{B})$, we obtain a compact formulation for diffusion velocities and heat flux

$$
\begin{align*}
\boldsymbol{V}_{i} & =-\sum_{j \in \mathcal{S}} \boldsymbol{D}_{i j} \boldsymbol{d}_{j}-\boldsymbol{\theta}_{i} \boldsymbol{\partial}_{\boldsymbol{x}} \log T  \tag{111}\\
\boldsymbol{q} & =-\widehat{\boldsymbol{\lambda}} \boldsymbol{\partial}_{\boldsymbol{x}} T-p \sum_{i \in \mathcal{S}} \boldsymbol{\theta}_{i} \boldsymbol{d}_{i}+\sum_{i \in \mathcal{S}}\left(\frac{5}{2} k_{\mathrm{B}} T+\overline{\mathcal{E}_{i}}\right) n_{i} \boldsymbol{V}_{i} \tag{112}
\end{align*}
$$

However, for any set of coefficients $\mu^{\|}, \mu^{\perp}$, and $\mu^{\odot}$, such that $\mu^{\|}$is independent of $B, \mu^{\perp}-\mu^{\|}=$ $B^{2} \psi_{\mu}^{\perp}\left(B^{2}\right)$ and $\mu^{\odot}=B \psi_{\mu}^{\odot}\left(B^{2}\right)$, where the functions $\psi_{\mu}^{\perp}$ and $\psi_{\mu}^{\odot}$ are smooth, we directly obtain that the tensorial coefficient $\mu^{\|} \mathbf{M}^{\|}+\mu^{\perp} \mathbf{M}^{\perp}+\mu^{\odot} \mathbf{M}^{\odot}$ can be written

$$
\mu^{\|} \mathbf{M}^{\|}+\mu^{\perp} \mathbf{M}^{\perp}+\mu^{\odot} \mathbf{M}^{\odot}=\mu^{\|} \boldsymbol{I}+\psi_{\mu}^{\perp}\left(B^{2}\right)\left(B^{2} \mathbb{I}-\boldsymbol{B} \otimes \boldsymbol{B}\right)+\psi_{\mu}^{\odot}\left(B^{2}\right) \boldsymbol{R}(\boldsymbol{B}),
$$

since $\boldsymbol{B}=B \boldsymbol{B}$ so that $\mu^{\|} \mathbf{M}^{\|}+\mu^{\perp} \mathbf{M}^{\perp}+\mu^{\odot} \mathbf{M}^{\odot}$ is smooth for any $\boldsymbol{B}$ and converges towards $\mu^{\|} \boldsymbol{I}$ as $\boldsymbol{B} \rightarrow 0$. As a consequence, the heat and mass diffusion fluxes are smooth functions of the magnetic field and we obtain in the limit case $\boldsymbol{B} \rightarrow 0$ the same contributions as with a zero magnetic field.

### 6.2 Momentum transport coefficients

We first note that the volume viscosity $\kappa$ does not depend on the magnetic field. Similarly, since the operators $\mathcal{F}^{\mathcal{S}}$ and $\mathcal{F}^{z, m}$ do not depend on $\boldsymbol{B}$, the function $\boldsymbol{\varphi}_{i}^{\eta[1]}$ does not depend on the magnetic field. On the other hand, in order to study the dependence on the magnetic field of the shear viscosities, we expand the functions $\varphi^{\eta[2]}$ and $\varphi^{\eta[3]}$ in the form

$$
\begin{equation*}
\boldsymbol{\varphi}_{i}^{\eta[2]}=\sum_{n \in \mathbb{N}}(2 \mathrm{i} B)^{n} \boldsymbol{\varphi}_{i, n}^{\eta}, \quad \boldsymbol{\varphi}_{i}^{\eta[3]}=\sum_{n \in \mathbb{N}}(\mathrm{i} B)^{n} \boldsymbol{\varphi}_{i, n}^{\eta} \tag{113}
\end{equation*}
$$

where the functions $\boldsymbol{\varphi}_{\cdot, n}^{\eta}=\left(\boldsymbol{\varphi}_{i, n}^{\eta}\right)_{i \in \mathcal{S}}, n \in \mathbb{N}$, do not depend on the magnetic field and satisfy the integro-differential equations

$$
\begin{align*}
& \mathcal{F}^{\mathcal{S}}\left(\boldsymbol{\varphi}_{\cdot, 0}^{\eta}\right)=\boldsymbol{\Psi}^{\eta}, \quad \mathcal{F}^{\mathcal{S}}\left(\boldsymbol{\varphi}_{\cdot, n+1}^{\eta}\right)=-\mathcal{F}^{z, m}\left(\boldsymbol{\varphi}_{., n}^{\eta}\right), \quad n \geq 0  \tag{114}\\
&\left\langle\left\langle f^{0} \boldsymbol{\varphi}_{\cdot, n}^{\eta}, \psi^{l}\right\rangle\right\rangle=0, \quad l \in\left\{0, \ldots, n^{s}+4\right\} \tag{115}
\end{align*}
$$

These equations yield existence and uniqueness of $\varphi_{i, n}^{\eta}, i \in \mathcal{S}, n \in \mathbb{N}$, and we have the relations $\boldsymbol{\varphi}_{i}^{\eta[1]}=\boldsymbol{\varphi}_{i, 0}^{\eta}, i \in \mathcal{S}$. Relations (113) yield the following expansions for the shear viscosities

$$
\begin{align*}
& \eta_{1}=\frac{1}{10} k_{\mathrm{B}} T \llbracket \boldsymbol{\varphi}_{\cdot, 0}^{\eta}, \boldsymbol{\varphi}_{\cdot, 0}^{\eta} \rrbracket+\frac{1}{20} k_{\mathrm{B}} T \sum_{N \in \mathbb{N}^{*}}(-1)^{N} 2^{2 N} B^{2 N} \sum_{n+m=2 N}(-1)^{m} \llbracket \boldsymbol{\varphi}_{\cdot, n}^{\eta}, \boldsymbol{\varphi}_{\cdot, m}^{\eta} \rrbracket,  \tag{116}\\
& \eta_{2}=-\frac{1}{10} k_{\mathrm{B}} T \sum_{N \in \mathbb{N}}(-1)^{N} 2^{2 N} B^{2 N+1} \sum_{n+m=2 N}(-1)^{m}\left(\left(\boldsymbol{\varphi}_{\cdot, n}^{\eta}, \boldsymbol{\varphi}_{\cdot,, m}^{\eta}\right)\right),  \tag{117}\\
& \eta_{3}=-\frac{1}{20} k_{\mathrm{B}} T \sum_{N \in \mathbb{N}^{*}}(-1)^{N} 2^{2 N} B^{2 N} \sum_{n+m=2 N}(-1)^{m} \llbracket \boldsymbol{\varphi}_{\cdot, n}^{\eta}, \boldsymbol{\varphi}_{\cdot, m}^{\eta} \rrbracket,  \tag{118}\\
& \eta_{4}=-\frac{1}{20} k_{\mathrm{B}} T \sum_{N \in \mathbb{N}^{*}}(-1)^{N}\left(2^{2 N}-2\right) B^{2 N} \sum_{n+m=2 N}(-1)^{m} \llbracket \boldsymbol{\varphi}_{\cdot, n}^{\eta}, \boldsymbol{\varphi}_{\cdot, m}^{\eta} \rrbracket  \tag{119}\\
& \eta_{5}=\frac{1}{10} k_{\mathrm{B}} T \sum_{N \in \mathbb{N}^{*}}(-1)^{N}\left(2^{2 N}-1\right) B^{2 N+1} \sum_{n+m=2 N}(-1)^{m}\left(\left(\boldsymbol{\varphi}_{\cdot, n}^{\eta}, \boldsymbol{\varphi}_{\cdot, m}^{\eta}\right)\right) . \tag{120}
\end{align*}
$$

As a consequence, there exist smooth functions $\zeta_{1}, \zeta_{2}, \zeta_{3}, \zeta_{4}, \zeta_{5}, \zeta_{6}$, of $B^{2}$ such that

$$
\begin{gather*}
\eta_{1}=\zeta_{1}\left(B^{2}\right), \quad \eta_{2}=B \zeta_{2}\left(B^{2}\right), \quad \eta_{3}=B^{2} \zeta_{3}\left(B^{2}\right), \quad \eta_{4}=B^{2} \zeta_{4}\left(B^{2}\right)  \tag{121}\\
\eta_{5}=B^{3} \zeta_{5}\left(B^{2}\right), \quad 2 \eta_{4}-\eta_{3}=B^{4} \zeta_{6}\left(B^{2}\right) \tag{122}
\end{gather*}
$$

Note in particular the relation $2 \eta_{4}-\eta_{3}=B^{4} \varphi_{6}\left(B^{2}\right)$ which is not straightforward to devise intuitively. It is then possible to rewrite the viscous tensor as a smooth function of the magnetic field in the form

$$
\begin{aligned}
-\boldsymbol{\Pi} & =\kappa\left(\boldsymbol{\partial}_{\boldsymbol{x}} \cdot \boldsymbol{v}\right) \boldsymbol{I}+\zeta_{1}\left(B^{2}\right) \mathbf{S}+\zeta_{2}\left(B^{2}\right)(\boldsymbol{R}(\boldsymbol{B}) \mathbf{S}-\mathbf{S} \boldsymbol{R}(\boldsymbol{B}))-\zeta_{3}\left(B^{2}\right) \boldsymbol{R}(\boldsymbol{B}) \mathbf{S} \boldsymbol{R}(\boldsymbol{B}) \\
- & \zeta_{6}\left(B^{2}\right) \boldsymbol{B}^{t} \mathbf{S} \boldsymbol{B} \boldsymbol{B} \otimes \boldsymbol{B}+\zeta_{4}\left(B^{2}\right)(\mathbf{S} \boldsymbol{B} \otimes \boldsymbol{B}+\boldsymbol{B} \otimes \boldsymbol{B} \mathbf{S}) \\
& +\zeta_{5}\left(B^{2}\right)(\boldsymbol{B} \otimes \boldsymbol{B} \mathbf{S} \boldsymbol{R}(\boldsymbol{B})-\boldsymbol{R}(\boldsymbol{B}) \mathbf{S} \boldsymbol{B} \otimes \boldsymbol{B})
\end{aligned}
$$

using $\boldsymbol{B}=B \mathcal{B}$ so that $\boldsymbol{\Pi}$ is a smooth function of $\boldsymbol{B}$. Hence we obtain in the limit case the same contribution as with a zero magnetic field for the viscous stress tensor since $\zeta_{1}(0)=\eta_{1}(0)=$ $\frac{1}{10} k_{\mathrm{B}} T \llbracket \boldsymbol{\varphi}^{\eta(1)}, \boldsymbol{\varphi}^{\eta(1)} \rrbracket$.

## 7 Onsager reciprocal relations

Onsager relations are symmetry properties which must hold between the transport coefficients. These constraints express the invariance of phenomena by time reversal transformation. In the framework of the kinetic theroy of gases, these symmetry properties can directly be deduced from the symmetry properties of the linearized collision operator $[3,13,21,24]$.

Using the tensorial relations $(111)(112)$, Onsager reciprocal relations require that

$$
\boldsymbol{D}_{i j}(-\boldsymbol{B})=\boldsymbol{D}_{j i}(\boldsymbol{B})^{t}, \quad \boldsymbol{\theta}_{i}(-\boldsymbol{B})=\boldsymbol{\theta}_{i}(\boldsymbol{B})^{t}, \quad \widehat{\boldsymbol{\lambda}}(-\boldsymbol{B})=\widehat{\boldsymbol{\lambda}}(\boldsymbol{B})^{t}
$$

and these equalities are easily estalished since the matrices $\mathbf{M}^{\|}$and $\mathbf{M}^{\perp}$ are symmetric, the matrix $\mathbf{M}^{\odot}$ is antisymmetric, the matrices $\mathbf{M}^{\|}$and $\mathbf{M}^{\perp}$ are even functions of $\boldsymbol{B}$ the matrix $\mathbf{M}^{\odot}$ is odd function of $\boldsymbol{B}$, the transport coefficients $D_{i j}^{\|}, D_{i j}^{\perp}, D_{i j}^{\odot}, i, j \in \mathcal{S}, \theta_{i}^{\|}, \theta_{i}^{\perp}, \theta_{i}^{\odot}, i \in \mathcal{S}, \widehat{\lambda}^{\|}, \widehat{\lambda}^{\perp}, \widehat{\lambda}^{\odot}$ are even functions of $\boldsymbol{B}$ because they only depend on the norm $B$ of the magnetic field, and the transport coefficients satisfy $D_{i j}^{\|}=D_{j i}^{\|}, D_{i j}^{\perp}=D_{j i}^{\perp}, D_{i j}^{\odot}=D_{j i}^{\odot}, i, j \in \mathcal{S}$, as a result of (50), (54), and (55).

In order to express Onsager relations for viscosity coefficients, we rewrite the three columns of the viscous stress tensor in the form

$$
\boldsymbol{\Pi}_{i}=-\sum_{j=1}^{3}\left(\kappa \mathbf{M}_{i j}^{\kappa}+\eta_{1} \mathbf{M}_{i j}^{\eta_{1}}+\eta_{2} \mathbf{M}_{i j}^{\eta_{2}}+\eta_{3} \mathbf{M}_{i j}^{\eta_{3}}+\eta_{4} \mathbf{M}_{i j}^{\eta_{4}}+\eta_{5} \mathbf{M}_{i j}^{\eta_{5}}\right) \partial_{i} \boldsymbol{v}, \quad i \in\{1,2,3\}
$$

where $\boldsymbol{\Pi}_{i}$ is the $i^{\text {th }}$ column of $\boldsymbol{\Pi}, i \in\{1,2,3\}$ and the matrices $\mathbf{M}_{i j}^{\kappa}, \mathbf{M}_{i j}^{\eta_{\alpha}}, i, j \in\{1,2,3\}, \alpha \in$ $\{1,2,3,4,5\}$, are defined by

$$
\begin{aligned}
& \mathbf{M}_{i j}^{\kappa}=\boldsymbol{e}_{i} \otimes \boldsymbol{e}_{j}, \\
& \mathbf{M}_{i j}^{\eta_{1}}=\delta_{i j} \boldsymbol{I}+\boldsymbol{e}_{j} \otimes \boldsymbol{e}_{i}-\frac{2}{3} \boldsymbol{e}_{i} \otimes \boldsymbol{e}_{j}, \\
& \mathbf{M}_{i j}^{\eta_{2}}=2 \delta_{i j} \boldsymbol{R}(\mathcal{B})+\boldsymbol{R}\left(\boldsymbol{e}_{i}\right) \boldsymbol{R}(\mathcal{B}) \boldsymbol{R}\left(\boldsymbol{e}_{j}\right)+2 \boldsymbol{e}_{i}^{t} \boldsymbol{R}(\mathcal{B}) \boldsymbol{e}_{j} \boldsymbol{I}, \\
& \mathbf{M}_{i j}^{\eta_{3}}=2 \mathcal{B}_{i} \mathcal{B}_{j} \boldsymbol{B} \otimes \mathcal{B}-\frac{2}{3} \boldsymbol{e}_{i} \otimes \boldsymbol{e}_{j}+2 \boldsymbol{R}(\mathcal{B}) \boldsymbol{e}_{j} \otimes \boldsymbol{e}_{i} \boldsymbol{R}(\mathcal{B})-\boldsymbol{R}(\mathcal{B}) \boldsymbol{e}_{i} \otimes \boldsymbol{e}_{j} \boldsymbol{R}(\mathcal{B}), \\
& \mathbf{M}_{i j}^{\eta_{4}}=-4 \mathcal{B}_{i} \mathcal{B}_{j} \boldsymbol{B} \otimes \mathcal{B}+\mathcal{B}_{i} \mathcal{B}_{j} \boldsymbol{I}+\delta_{i j} \mathcal{B} \otimes \mathcal{B}+\mathcal{B}_{i} \boldsymbol{e}_{j} \otimes \mathcal{B}+\mathcal{B}_{j} \mathcal{B} \otimes \boldsymbol{e}_{i}, \\
& \mathbf{M}_{i j}^{\eta_{5}}=-2 \mathcal{B}_{i} \mathcal{B}_{j} \boldsymbol{R}(\mathcal{B})-\boldsymbol{R}\left(\boldsymbol{e}_{i}\right) \boldsymbol{R}(\mathcal{B}) \boldsymbol{R}\left(\boldsymbol{e}_{j}\right)-2 \boldsymbol{e}_{i}^{t} \boldsymbol{R}(\mathcal{B}) \boldsymbol{e}_{j} \mathcal{B} \otimes \mathcal{B},
\end{aligned}
$$

with $\left(\boldsymbol{e}_{1}, \boldsymbol{e}_{2}, \boldsymbol{e}_{3}\right)$ the canonical basis. Onsager relations require that

$$
\begin{aligned}
\left(\kappa \mathbf{M}_{i j}^{\kappa}+\eta_{1} \mathbf{M}_{i j}^{\eta_{1}}+\right. & \left.\eta_{2} \mathbf{M}_{i j}^{\eta_{2}}+\eta_{3} \mathbf{M}_{i j}^{\eta_{3}}+\eta_{4} \mathbf{M}_{i j}^{\eta_{4}}+\eta_{5} \mathbf{M}_{i j}^{\eta_{5}}\right)(-\boldsymbol{B})= \\
& \left(\kappa \mathbf{M}_{j i}^{\kappa}+\eta_{1} \mathbf{M}_{j i}^{\eta_{1}}+\eta_{2} \mathbf{M}_{j i}^{\eta_{2}}+\eta_{3} \mathbf{M}_{j i}^{\eta_{3}}+\eta_{4} \mathbf{M}_{j i}^{\eta_{4}}+\eta_{5} \mathbf{M}_{j i}^{\eta_{5}}\right)^{t}(\boldsymbol{B}), \quad i, j \in\{1,2,3\},
\end{aligned}
$$

but these equalities are easily established since the matrix $\boldsymbol{R}(\boldsymbol{X})$ is antisymmetric for any vector $\boldsymbol{X}$, the matrix $\boldsymbol{R}(\boldsymbol{B})$ is odd function of $\boldsymbol{B}$, the viscosities $\kappa, \eta_{\alpha}, \alpha \in\{1,2,3,4,5\}$, are even functions of $\boldsymbol{B}$ because they only depend on the norm of the magnetic field.

## Acknowledgements

The authors would like to thank Doctor Domenico Bruno from Istituto di Metodologie Inorganiche e dei Plasmi del CNR in Bari for first spotting the sign error in the transverse coefficients bracket expressions overlooked in [25].

Appendix Erratum for 'Kinetic theory of partially ionized reactive gas mixtures', published in Physica A 327 (2003) pp. 313-348

In this appendix, we report a number of misprints and errors overlooked in our previous publication on the kinetic theory of partially ionized gas mixtures. The authors are very grateful to Doctor Domenico Bruno from Istituto di Metodologie Inorganiche e dei Plasmi del CNR in Bari for first spotting the sign error in the transverse coefficients bracket expressions. Note also that the transverse components are denoted with the superscript ${ }^{t}$ in [Physica A 327 (2003) pp. 313-348] instead of ${ }^{\odot}$ in this report.

## Section 5.2

- On page 332, below Equation (5.9), the formulas for the transport coefficients should be $D_{i j}^{\|}=\left(p k_{\mathrm{B}} T / 3\right)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{D_{j}(1)}, \boldsymbol{\Psi}^{D_{i}}\right\rangle\right\rangle, D_{i j}^{\perp}+\mathrm{i} D_{i j}^{t}=\left(p k_{\mathrm{B}} T / 3\right)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{D_{j}(2)}, \boldsymbol{\Psi}^{D_{i}}\right\rangle\right\rangle$, and $\theta_{i}^{\|}=-(1 / 3)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\widehat{\lambda}(1)}, \boldsymbol{\Psi}^{D_{i}}\right\rangle\right\rangle, \theta_{i}^{\perp}+\mathrm{i} \theta_{i}^{t}=-(1 / 3)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\widehat{\lambda}(2)}, \boldsymbol{\Psi}^{D_{i}}\right\rangle\right\rangle$.
- On page 332, Equations (5.11) and (5.13) should be

$$
\begin{gather*}
D_{i j}^{\perp}+\mathrm{i} D_{i j}^{t}=\frac{1}{3} p k_{\mathrm{B}} T\left(\llbracket \boldsymbol{\varphi}^{D_{i}(2)}, \boldsymbol{\varphi}^{D_{j}(2)} \rrbracket-\mathrm{i}\left(\left(\varphi^{D_{i}(2)}, \varphi^{D_{j}(2)}\right)\right)\right),  \tag{5.11}\\
\theta_{i}^{\perp}+\mathrm{i} \theta_{i}^{t}=-\frac{1}{3}\left(\llbracket \boldsymbol{\varphi}^{D_{i}(2)}, \boldsymbol{\varphi}^{\widehat{\lambda}(2)} \rrbracket-\mathrm{i}\left(\left(\boldsymbol{\varphi}^{D_{i}(2)}, \boldsymbol{\varphi}^{\widehat{\lambda}(2)}\right)\right)\right) . \tag{5.13}
\end{gather*}
$$

- On page 333 , after the second paragraph, $D_{i j}^{\perp}$ and $D_{i j}^{t}$ should be

$$
\begin{gathered}
D_{i j}^{\perp}=\frac{1}{3} p k_{\mathrm{B}} T\left(\Re \llbracket \boldsymbol{\varphi}^{D_{i}(2)}, \boldsymbol{\varphi}^{D_{j}(2)} \rrbracket-\Im\left(\left(\boldsymbol{\varphi}^{D_{i}(2)}, \boldsymbol{\varphi}^{D_{j}(2)}\right)\right)\right)=\frac{1}{3} p k_{\mathrm{B}} T \Re \llbracket \boldsymbol{\varphi}^{D_{i}(2)}, \boldsymbol{\varphi}^{D_{j}(2)} \rrbracket, \\
D_{i j}^{t}=-\frac{1}{3} p k_{\mathrm{B}} T\left(\Im \llbracket \boldsymbol{\varphi}^{D_{i}(2)}, \boldsymbol{\varphi}^{D_{j}(2)} \rrbracket+\Re\left(\left(\boldsymbol{\varphi}^{D_{i}(2)}, \boldsymbol{\varphi}^{D_{j}(2)}\right)\right)=-\frac{1}{3} p k_{\mathrm{B}} T \Re\left(\left(\boldsymbol{\varphi}^{D_{i}(2)}, \boldsymbol{\varphi}^{D_{j}(2)}\right)\right) .\right.
\end{gathered}
$$

We also have seen that $\Im \llbracket \varphi^{D_{i}(2)}, \varphi^{D_{j}(2)} \rrbracket=0$ and $\Im\left(\left(\varphi^{D_{i}(2)}, \varphi^{D_{j}(2)}\right)\right)=0$, in such a way that $\llbracket \varphi^{D_{i}(2)}, \varphi^{D_{j}(2)} \rrbracket=\Re \llbracket \varphi^{D_{i}(2)}, \varphi^{D_{j}(2)} \rrbracket$ and $\left(\left(\varphi^{D_{i}(2)}, \varphi^{D_{j}(2)}\right)\right)=\Re\left(\left(\varphi^{D_{i}(2)}, \varphi^{D_{j}(2)}\right)\right)$.

- On page 334, the last line should be

$$
p \sigma^{\|}=\sum_{i, j \in \mathcal{S}} D_{i j}^{\|} n_{i} e_{i} n_{j} e_{j}, \quad p \sigma^{\perp}=\sum_{i, j \in \mathcal{S}} D_{i j}^{\perp} n_{i} e_{i} n_{j} e_{j}, \quad p \sigma^{t}=\sum_{i, j \in \mathcal{S}} D_{i j}^{t} n_{i} e_{i} n_{j} e_{j}
$$

## Section 5.3

- On page 335, after Equation (5.21), the formulas defining the transport coefficients should be $\quad \hat{\lambda}^{\|}=\left(1 / 3 k_{\mathrm{B}} T^{2}\right)\left\langle\left\langle f^{0} \varphi^{\widehat{\lambda}(1)}, \boldsymbol{\Psi}^{\widehat{\lambda}}\right\rangle\right\rangle, \quad \widehat{\lambda}^{\perp}+\mathrm{i} \widehat{\lambda}^{t}=\left(1 / 3 k_{\mathrm{B}} T^{2}\right)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{\widehat{\lambda}(2)}, \boldsymbol{\Psi}^{\widehat{\lambda}}\right\rangle\right\rangle$, and $\widehat{\theta}_{i}^{\|}=-(1 / 3)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{D_{i}(1)}, \boldsymbol{\Psi}^{\widehat{\lambda}}\right\rangle\right\rangle, \widehat{\theta}_{i}^{\perp}+\mathrm{i} \widehat{\theta}_{i}^{t}=-(1 / 3)\left\langle\left\langle f^{0} \boldsymbol{\varphi}^{D_{i}(2)}, \boldsymbol{\Psi}^{\widehat{\lambda}}\right\rangle\right\rangle$. We have also seen, however, thanks to the new symmetry properties of the transport coefficients, that $\widehat{\theta}_{i}^{\|}=\theta_{i}^{\|}, \quad \widehat{\theta}_{i}^{\perp}=\theta_{i}^{\perp}$, and $\widehat{\theta}_{i}^{t}=\theta_{i}^{t}, i \in \mathcal{S}$.
- On page 335 , before the last paragrpah, the expressions for $\widehat{\lambda}^{\perp}+\mathrm{i} \widehat{\lambda}^{t}$ and $\widehat{\theta}_{i}^{\perp}+\mathrm{i} \widehat{\theta}_{i}^{t}$ should be

$$
\begin{aligned}
& \widehat{\lambda}^{\perp}+\mathrm{i} \widehat{\lambda}^{t}=\frac{1}{3 k_{\mathrm{B}} T^{2}}\left(\llbracket \varphi^{\widehat{\lambda}(2)}, \varphi^{\widehat{\lambda}(2)} \rrbracket-\mathrm{i}\left(\left(\varphi^{\widehat{\lambda}(2)}, \varphi^{\widehat{\lambda}(2)}\right)\right)\right), \\
& \widehat{\theta}_{i}^{\perp}+\mathrm{i} \widehat{\theta}_{i}^{t}=-\frac{1}{3}\left(\llbracket \varphi^{\widehat{\lambda}(2)}, \varphi^{D_{i}(2)} \rrbracket-\mathrm{i}\left(\left(\boldsymbol{\varphi}^{\widehat{\lambda}(2)}, \varphi^{D_{i}(2)}\right)\right)\right) .
\end{aligned}
$$

## Section 5.7

- On page 340 , before the last paragraph, the last term in the expression of $\Upsilon_{v}$ should be $\sum_{i, j \in \mathcal{S}} D_{i j}^{t} \boldsymbol{d}_{i}^{\perp} \cdot \boldsymbol{d}_{j}^{t}$, and this term vanishes thanks to the symmetry properties of transport coefficients and since $\boldsymbol{d}_{i}^{\perp} \cdot \boldsymbol{d}_{j}^{t}=-\boldsymbol{d}_{i}^{t} \cdot \boldsymbol{d}_{j}^{\perp}$.
- On page 340 , in the last line, the second term should be $\left\langle A^{t} x^{\perp}, x^{t}\right\rangle, x_{0}$ should be $x_{0}=$ $\left(\partial_{\alpha} \log T\right)^{\perp}$ and $y_{0}$ should be $y_{0}=\left(\partial_{\alpha} \log T\right)^{t}$.

## Section 5.8

- The discussion about Onsager reciprocal relations is not fully satisfactory. It should be replaced by the detailed discussion presented in Section 7 of this paper which includes a discussion of the viscous tensor.

## Section 6.1

- On page 343, after Equation (6.4), the definition of $\beta_{k}^{r}$ should be

$$
\beta_{k}^{r}=\left\langle\left\langle f^{0} \psi^{\mu}, \xi^{r k}\right\rangle\right\rangle
$$

- On page 343 , in the middle of the page, the constraint vectors $\mathcal{G}_{k}^{\text {rlv }}$ should be

$$
\mathcal{G}_{k}^{r l \nu}=\left\langle\left\langle f^{0} \xi^{r k}, \mathcal{T}_{\nu} \psi^{l}\right\rangle\right\rangle, \quad l \in\left\{1, \ldots, n^{s}+4\right\}, \nu \in\left\{1, \ldots, n^{\tau}\right\}
$$
